# Shadow Rates as a Measure of the Monetary Policy Stance: Some International Evidence

## Abstract

This paper examines the usefulness of shadow rates to measure the monetary policy stance by comparing them to the official policy rates and those implied by three types of Taylor rules in both inflation targeting countries (the UK, Canada, Australia and New Zealand) and others that have only targeted inflation at times (the US, Japan, the Euro Area and Switzerland) over the period from the early 1990s to December 2021. Shadow rates estimated from a dynamic factor model are shown to suggest a much looser policy stance than either the official policy rates or those implied by the Taylor rules, and generally to provide a more accurate picture of the monetary policy stance during both ZLB and non-ZLB periods, since they reflect the full range of unconventional policy measures used by central banks. Further, generalised impulse response analysis based on two alternative Vector Autoregression (VAR) models indicates that monetary shocks based on the shadow rates are more informative than those related to the official policy rates, especially during the Global Financial Crisis and the recent Covid-19 pandemic, when unconventional measures have been adopted.

JEL-Codes: C380, E430, E520, E580.

Keywords: dynamic factor models, shadow rates, inflation targeting, monetary policy stance.

## 1. Introduction

In recent years, a number of countries have had to lower interest rates to near-zero levels and to adopt unconventional measures to mitigate the impact of the Global Financial Crisis and of the Covid-19 pandemic on financial markets and the economy as a whole. As a result, it has become less straightforward to assess the monetary policy stance, since official policy rates do not reflect the full range of measures adopted by central banks. It has therefore been suggested that shadow rates taking those into account might be more informative about monetary policy. This issue has been analysed in several papers. For example, Lombardi and Zhu (2018) estimated shadow rates using dynamic factor models and compared them to those implied by the Taylor rule and the actual Federal Funds rate in the US; they showed that shadow rates are a more accurate measure of monetary policy during the zero lower bound (ZLB) period, i.e. when the Federal Funds rate was near zero. <sup>1</sup> Bernanke et al. (2019) also showed that shadow rates obtained from stochastic simulation models represent the monetary policy stance well for the US and deliver better economic outcomes during the ZLB period than Taylor rule implied rates. Wu and Zhang (2019), on the other hand, found that Taylor rules are able to explain the behaviour of the shadow rate during both ZLB and non-ZLB periods and thus provide a more accurate picture of monetary policy.

This paper revisits these issues and extends previous work in two ways. First, it carries out the analysis for a wider set of countries including both inflation targeting ones (namely the UK, Canada, Australia and New Zealand), and others which have targeted the inflation rate only at times (more precisely the US, Japan, the Euro Area and Switzerland). Second, it includes the Covid-19 pandemic period. Using shadow rates computed from a dynamic factor model, it assesses their usefulness to measure the monetary policy stance by comparing them to the official policy rates and those to implied by three types of Taylor rules (namely a classical, an extended and an interest rate smoothing Taylor rule). It then also examines monetary policy shocks based on shadow and official rates respectively to establish how informative they are. These are obtained by estimating generalised impulse response functions (Pesaran and Shin, 1998) from two alternative Vector Autoregression (VAR) models; using this method, which, unlike others, is invariant to the ordering of the variables, is an additional contribution of our study to the literature on this topic.

---

<sup>1</sup> The ZLB period is normally defined as any period during which the official central bank policy rate was at or below 25 basis points; this definition is also used in the present paper.

The remainder of the paper is structured as follows: Section 2 briefly reviews the relevant literature; Section 3 outlines the methodology used for the analysis; Section 4 discusses the data and the empirical results; Section 5 offers some concluding remarks.

## **2. Literature Review**

The literature on the effects of unconventional monetary policy includes numerous papers constructing shadow policy rates and comparing them to those implied by monetary policy rules. For instance, Bauer and Rudebusch (2013) obtained shadow rates from dynamic term structure models and found that they were similar to the policy rates based on a Taylor rule; however, they advised against using the former to evaluate the monetary policy stance owing to their model-dependence and the limited information provided for this purpose by the short end of the term structure. Lombardi and Zhu (2018) also used a dynamic factor model to estimate a shadow policy rate for the US, and reported that this tracks the Federal Funds rate very closely both during ZLB and non-ZLB periods and is a good measure of the policy stance vis-à-vis Taylor rule benchmarks; moreover, they showed that monetary policy shocks estimated from VAR models including the shadow rate provide a much more accurate picture of monetary policy than those based on the official policy rate during periods characterised by unconventional measures.

Bernanke et al. (2019) analysed ten different monetary policy rules at the ZLB and found that shadow rate rules (in which the first difference of the shadow rate depends on the weighted sum of the inflation and output gaps) outperform Taylor rules. Wu and Zhang (2019) developed a New Keynesian model with a shadow rate which captures both the standard interest rate rule during normal times and unconventional monetary policy during the ZLB period; in the latter the central bank follows a shadow rate Taylor rule implying a negative rate which is achieved through measures such as quantitative easing (QE) and lending policies; moreover, the shadow rate is found to track very well an index of financial conditions which is strongly correlated with the Fed's balance sheet. Ajevskis (2020) estimated a natural rate of interest from a shadow rate term structure model for the Euro Area and the US and used it in the balance-approach version of the Taylor rule; he found that the rates implied by the latter were in line with the official policy ones. Ellington (2021) extended the model by Wu and Zhang (2019) and

investigated the effectiveness of unconventional monetary policies under a binding ZLB constraint using time-varying coefficient VAR models of the shadow rate implied by the Taylor rules. He found that the shadow rate is a useful indicator of the monetary policy stance and that the sensitivity of economic fundamentals to shadow rate shocks has remained unchanged during the ZLB period, while that of GDP growth and inflation to Federal funds rate shocks has increased.

It should be noted that there are different possible ways to estimate shadow rates, the three most commonly used ones being three-factor term structure models (Wu and Xia, 2016), two-factor affine term structure models (Krippner, 2015a), and dynamic factor models (Lombardi and Zhu, 2018). The available empirical evidence suggests that the two-factor models produce the shadow rates most closely tracking the official policy rate and provide the most accurate assessment of the monetary policy stance during ZLB periods (Krippner, 2015b; Anderl and Caporale, 2022). However, shadow rates based on yield curve parameters generally contain a lot of noise, since they reflect market interest rate expectations which can be influenced by factors other than changes in monetary policy. By comparison, the dynamic factor model suggested by Lombardi and Zhu (2018), which extracts information from various central bank balance sheet items, is a much more reliable measure of the policy stance during unconventional periods.

### **3. Empirical Framework**

#### **3.1 Shadow Policy Rate Models**

Following Lombardi and Zhu (2018), we estimate the shadow rate by specifying a dynamic factor model of the following form:

$$X_t = \Lambda F_t + u_t \tag{1}$$

where  $X_t$  is a time series with  $T$  observations and dimension  $N$ ,  $F_t$  is an  $r \times 1$  vector of factors,  $\Lambda$  is an  $N \times r$  matrix of factor loadings and  $u_t$  are idiosyncratic components which are orthogonal to the factors. These are assumed to follow a VAR(p) process of the form:

$$F_t = \sum_{i=1}^p A_i F_{t-i} + e_t \quad (2)$$

where  $A_i$  is the coefficient matrix on past lags of the factors. Since both  $u_t$  and  $e_t$  are assumed to be *i. i. d.* and Gaussian, the dynamic factor model can be written in a state-space form and estimated with the Kalman filter. Economic variables are selected from a large dataset of monetary policy indicators to obtain the factors. The model is then estimated with the quasi maximum likelihood (QML) estimator based on the expectation maximisation (EM) algorithm proposed by Doz et al. (2012); this is similar to a two-step estimator but uses a Kalman filtering procedure which is iterated until EM convergence is achieved and is robust to model misspecification. Further, the Hallin-Liška (2007) and the Bai-Ng (2002) criteria are used to select the optimal number of factors in the model, whilst the lag length is chosen on the basis of the Bayesian-Schwarz information criterion.

### 3.2 Taylor Rule Interest Rates

We estimate the interest rate implied by the Taylor rule using three different types of rules commonly used by central banks. The first one is the classical Taylor rule which takes the following form:

$$i_t = \pi_t + \beta_\pi(\pi_t - \bar{\pi}) + \beta_y(y_t - \bar{y}_t) \quad (3)$$

where  $i_t$  is the central bank policy rate,  $\pi_t$  is the current rate of CPI inflation,  $\bar{\pi}$  is the target rate of inflation and  $y_t - \bar{y}_t$  is the output gap estimated using the Hodrick-Prescott filter (Hodrick and Prescott, 1997). We set  $\bar{\pi}$  equal to 2 for all countries, whilst the coefficients on the inflation gap  $\beta_\pi$  and the output gap  $\beta_y$  are set equal to 1.5 and 0.5 respectively (Taylor, 1993; Gerlach and Schnabel, 2000). The extended version of the Taylor rule for open economies which includes the real exchange rate is specified as follows:

$$i_t = \pi_t + \beta_\pi(\pi_t - \bar{\pi}) + \beta_y(y_t - \bar{y}_t) + \beta_q q_t \quad (4)$$

where  $q_t$  is the real effective exchange rate and all other variables are defined as before. The coefficient  $\beta_q$  on the real exchange rate is set equal to 0.25 following the existing literature in which it is normally between 0.25 and 0.5 (Froyen and Guender, 2018; Papadamou et al.,

2018), while the coefficients on the inflation and output gaps are again set equal to 1.5 and 0.5 respectively. Finally, we consider a Taylor rule with interest rate smoothing:

$$i_t = \rho i_{t-1} + (1 - \rho) \left( \pi_t + \beta_\pi (\pi_t - \bar{\pi}) + \beta_y (y_t - \bar{y}_t) \right) \quad (5)$$

where all variables are defined as before and  $\rho$  is the smoothing parameter measuring the gradual adjustment over time of the current interest rate to the target rate. In most empirical studies the interest rate smoothing parameter has been estimated to be between 0.78 to 0.92 (see, for instance, Amato and Laubach, 1999; Rudebusch, 2000; Sack and Wieland, 2000); we use its average value of 0.85 in our analysis.

### 3.3 A VAR Model with Monetary Policy Shocks

In order to assess the usefulness of the shadow rate to analyse monetary shocks, we estimate the following VAR model (henceforth VAR Model (1)) similar to Bernanke and Blinder (1992):

$$V_t = \sum_{i=1}^p B_i V_{t-i} + \varepsilon_t \quad (6)$$

where  $V_t$  is a vector of variables entering the model,  $B_i$  is the coefficient matrix and  $\varepsilon_t$  is a vector of error terms. The variables included are the log of real GDP and CPI inflation respectively and either the central bank policy rate or the shadow rate. We are then able to obtain two types of monetary policy shocks, one related to the shadow policy rate and the other to the official policy rate. For this purpose we estimate generalised impulse response functions which do not require orthogonalization of the shocks and are invariant to the ordering of the variables in the model (Pesaran and Shin, 1998). We also estimate a second VAR model (henceforth VAR Model (2)), similar to that suggested by Christiano et al. (1996), which includes the log of total reserves, the log of non-borrowed reserved and the log of a commodity price index as additional variables for the countries for which these series are available, i.e. the UK and the US. We use the Akaike information criterion to select the optimal lag length. The aim of the analysis is to establish whether shocks related to the shadow rates provide a more accurate picture of monetary policy during times when interest rates were near zero or negative.

## **4. Data and Empirical Results**

### **4.1 Data Description**

We use monthly data for the UK, Canada, Australia and New Zealand, namely countries which have adopted an official inflation targeting regime since the early 1990s, and also for the US, Japan, the Euro Area and Switzerland, which have instead had other frameworks in place and only targeted inflation at times. The sample ends in December 2021 in all cases, whilst the start date differs across countries depending on data availability (see Appendix A for details).

The central bank policy rates for all countries are taken from the Bank for International Settlements database. The source for the real GDP and CPI inflation series are the OECD Main Economic Indicators and Inflation (CPI) databases respectively for all countries, except for the inflation series for Australia and New Zealand, which are instead obtained from the Bank for International Settlements Consumer Price Index database. Real effective exchange rates are taken from the Bank for International Settlements Effective Exchange Rate Narrow Indices database for all countries. Commodity price indices and total non-borrowed reserves are from the Bank of England statistics database for the UK and from the Federal Reserve Bank of St Louis Economic database for the US, and total reserve data from the Federal Reserve Bank of St Louis economic database for both the UK and the US – these series are unfortunately not available for the other countries in our sample.

The dataset for the dynamic factor model includes variables from different categories, more precisely: (1) interest rates, (2) monetary aggregates, (3) balance sheet assets and (4) balance sheet liabilities. Details of these variables and their sources for all countries can be found in Appendix B. Including long-term yield data as well as central bank balance sheet items allows us to capture the full range of unconventional monetary policies ranging from forward guidance to large-scale asset purchases.

## 4.2 Shadow Policy Rates

**Figure 1 – Shadow Rate and Central Bank Policy Rate for Inflation Targeting Countries**

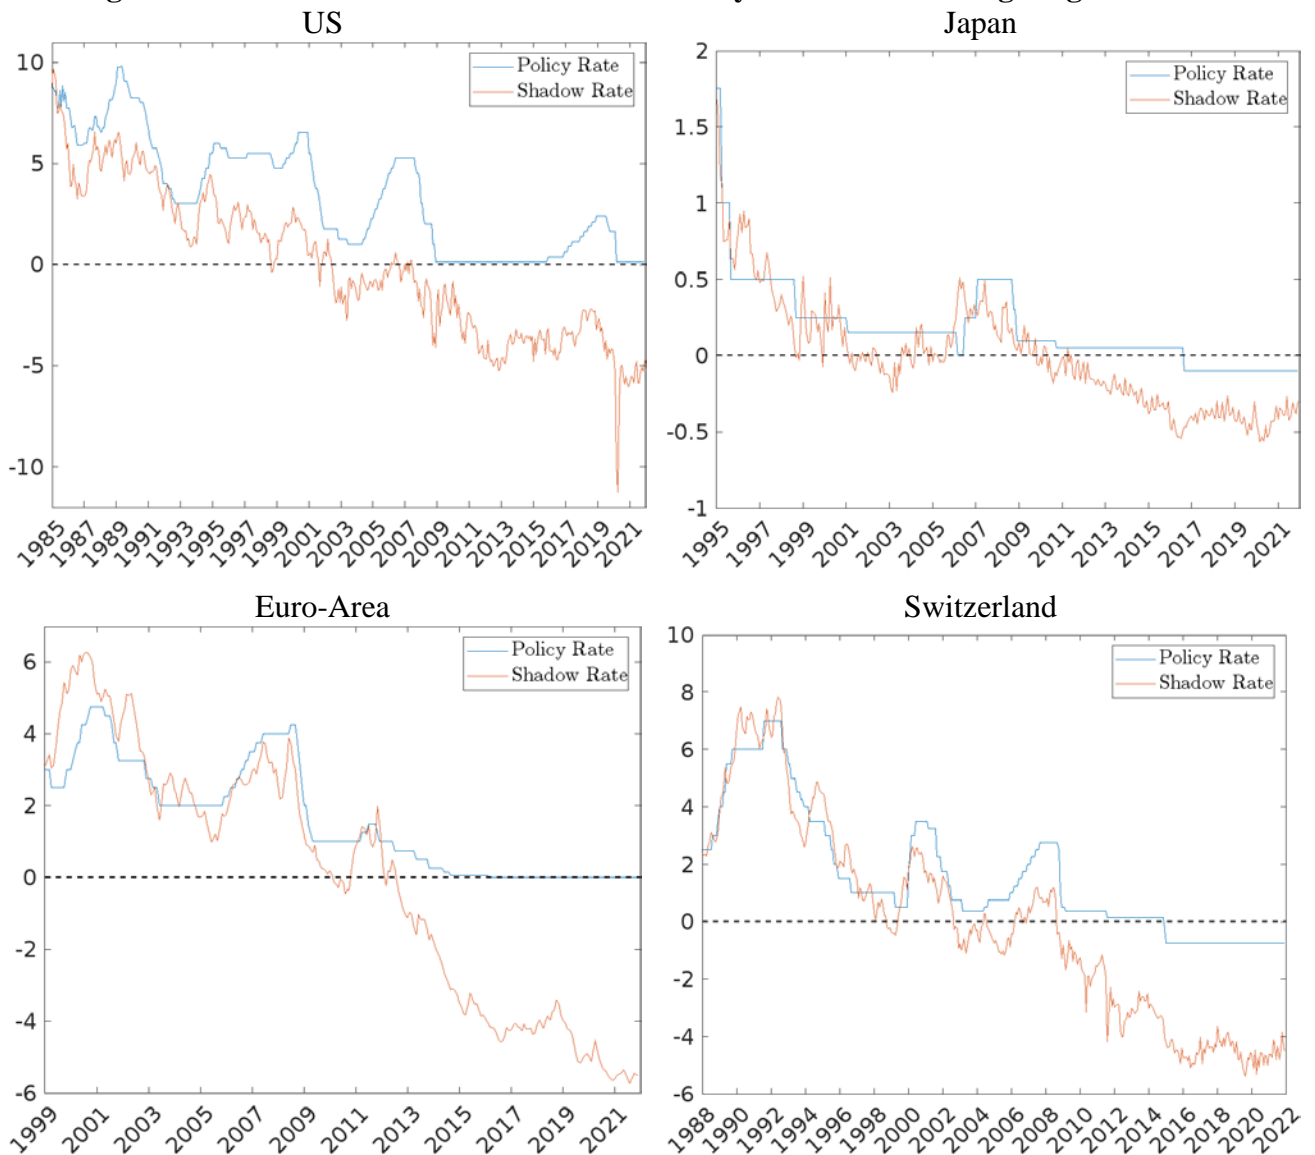

Figure 1 and 2 display the estimated shadow rates together with the official policy ones in the inflation targeting countries and the non-targeting ones respectively. It can be seen that the shadow rate tracks the official policy rate very closely during the non-ZLB period in the case of Canada, New Zealand, the Euro Area and Switzerland, but less closely in all other countries. In contrast to Lombardi and Zhu (2018), who focused on the US only, we find that shadow rates have tracked the policy rates less closely since the early 2000s in most countries: the former are based on a much wider range of policy indicators, whilst the latter do not accurately represent the full range of policy actions taken by central banks. In particular, during ZLB

periods, shadow rates turn negative for all countries, as they reflect the full range of unconventional monetary stimulus measures adopted by central banks during the Global Financial Crisis and the Covid-19 pandemic. Their behaviour implies that the monetary stance was in fact much looser than indicated by the official policy rate, even in the countries that allowed interest rates to become negative, i.e. Japan, the Euro Area and Switzerland.

**Figure 2 – Shadow Rate and Central Bank Policy Rate for Non-Targeting Countries**

### 4.3 Taylor Rule Implied Interest Rates

**Figure 3 – Policy Rate, Shadow Rate and Taylor Rule Rates for Inflation Targeting Countries**

Given that all countries in the sample have either adopted an inflation targeting regime or at least targeted the inflation rate at times, it is interesting to compare in each case the rate implied by the Taylor rule to both the official and the shadow rate to assess the monetary policy stance. Figures 3 and 4 plot all three series for inflation targeting and non-targeting countries, respectively. It is apparent that the interest rates implied by the Taylor rule with smoothing is the one tracking most closely the official policy rate in all countries. The rates implied by the classical and extended Taylor rules indicate that a much looser policy stance would have been required during the ZLB periods than that implied by the official rates, and even that in some cases negative rates would have been necessary. By contrast, the shadow rates are found to be

consistently negative, especially since the early 2000s, which suggests that unconventional policy measures resulted in actual rates much closer than the official ones to those consistent with the Taylor rules during the ZLB periods, whilst during non-ZLB periods the monetary stance was much looser than required by those rules.

It is also noticeable that the shadow rates in inflation targeting countries indicate a much looser policy stance compared to those implied by the Taylor rules than in non-targeting countries, i.e. that unconventional policies provided a greater stimulus in the former set of economies.

**Figure 4 – Policy Rate, Shadow Rate and Taylor Rule Rates for Non-Targeting Countries**

#### 4.4 VAR Model Results and Impulse Response Functions

Next we assess the usefulness of shadow rates to analyse monetary policy shocks. Figure 5 and 6 display the structural monetary policy shocks extracted from VAR model (1) as in Bernanke and Blinder (1996) for inflation targeting and non-targeting countries respectively. It is clear that shocks based on the shadow rates are more informative during unconventional periods (when they do not track closely the policy rate), since they capture the effects of the wide range of measures (such as asset purchases and QE) adopted by most countries during the Global Financial Crisis and the Covid-19 pandemic. By contrast, during normal periods, such as the 1990s, shocks based on the policy rates yield a sufficiently accurate picture.

**Figure 5 – Structural Monetary Policy Shocks from VAR Model (1) for Inflation Targeting Countries**

**Figure 6 – Structural Monetary Policy Shocks from VAR Model (1) for Non-Targeting Countries**

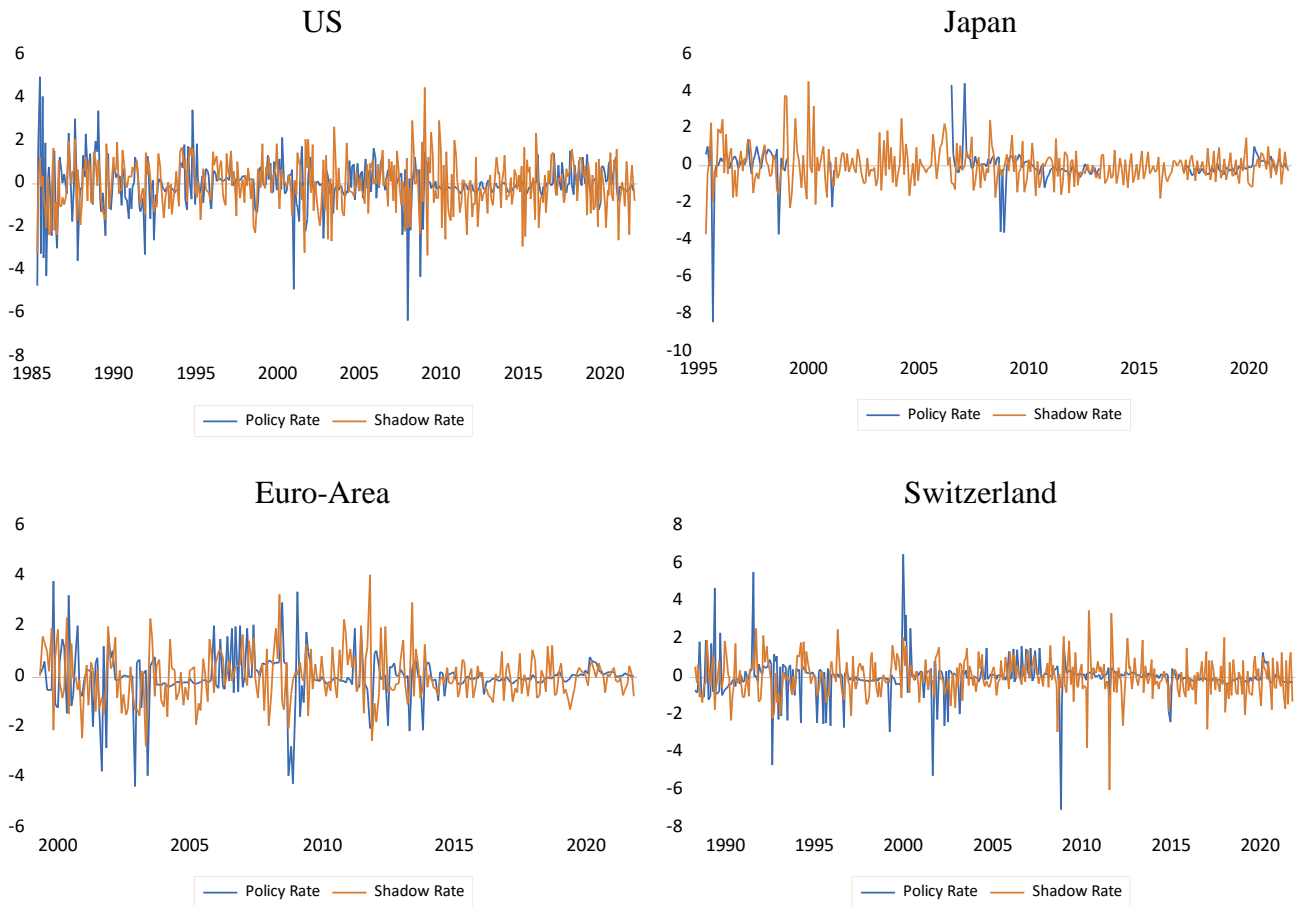

Figure 7 reports the structural monetary policy shocks estimated using the VAR Model (2) as in Christiano et al. (1996) - for the UK and US only, since the additional series required are only available for these two countries. On the whole the results are rather similar to the previous ones, and therefore it appears that VAR Model (1) might be sufficient to obtain an accurate picture of monetary policy in all countries in our sample. In other words, the additional variables included in VAR Model (2) to represent unconventional monetary policies (namely total and non-borrowed reserves), do not seem to play an important role.

**Figure 7 – Structural Monetary Policy Shocks from VAR Model (2) for the UK and the US**

## 5. Conclusions

This aim of this paper was to examine the usefulness of shadow rates to measure the monetary policy stance in both inflation targeting (the UK, Canada, Australia and New Zealand) and non-targeting countries (the US, Japan, the Euro Area and Switzerland) from the early 1990s until December 2021. A dynamic factor model was used to estimate the shadow rates, which were then compared to the official ones and to those implied by three different types of Taylor rules. Finally, generalised impulse functions from VAR models were estimated to obtain monetary shocks based on shadow and official rates respectively and assess how informative they are about monetary policy.

The results can be summarised as follows. First, the shadow rates suggest a much looser policy stance than either the official policy rates or those implied by three different types of Taylor rules, especially since the early 2000s, in all countries, even those that allowed their interest rates to become negative; this is because, unlike the policy rates, they reflect the full range of unconventional policy measures adopted by central banks: since they are constructed using term structure, monetary aggregate and balance sheet items, they provide a more comprehensive and accurate picture of the monetary policy stance. Second, monetary policy shocks based on the shadow rates are much more informative during unconventional periods (for the same reason specified before), whilst those based on the policy rates provide a sufficiently accurate picture during normal periods such as the 1990s. On the whole, our

analysis highlights the importance for policy-makers of using shadow rates to measure accurately the tightness/looseness of monetary policy stance and the effects of monetary policy shocks.

### 3. Australia

Variable	Description	Source	Transformation to induce stationarity
<b>Interest Rates</b>			
POLICYRATE	Central Bank Policy Rate	Bank for International Settlements	Natural logarithm
0.25	3-Month Treasury Bill	Reserve Bank of Australia	Natural logarithm
0.5	6-Month Treasury Bill	Reserve Bank of Australia	Natural logarithm
1	1-Year Treasury Rate	Reserve Bank of Australia	Natural logarithm
2	2-Year Treasury Rate	Reserve Bank of Australia	Natural logarithm
3	3-Year Treasury Rate	Reserve Bank of Australia	Natural logarithm
5	5-Year Treasury Rate	Reserve Bank of Australia	Natural logarithm
7	7-Year Treasury Rate	Reserve Bank of Australia	Natural logarithm
10	10-Year Treasury Rate	Reserve Bank of Australia	Natural logarithm
<b>Monetary Aggregates</b>			
M0	Monetary Base	Reserve Bank of Australia	Year-on-year growth rate
M1	Money Supply M1	OECD	Year-on-year growth rate
M2	Money Supply M2	Reserve Bank of Australia	Year-on-year growth rate
M3	Money Supply M3	Reserve Bank of Australia	Year-on-year growth rate
<b>Balance Sheet Assets</b>			
TA	Total Assets	Reserve Bank of Australia	First differences
TS	Total Securities Held Outright	Reserve Bank of Australia	First differences
DS	Debt Securities	Reserve Bank of Australia	First differences
<b>Balance Sheet Liabilities</b>			
CCY	Currency in Circulation	Reserve Bank of Australia	First differences
TR	Total Reserves	Reserve Bank of Australia	First differences
DD	Deposits of Depository Institutions	Reserve Bank of Australia	First differences
TL	Total Liabilities	Reserve Bank of Australia	First differences

#### 4. New Zealand

Variable	Description	Source	Transformation to induce stationarity
<b>Interest Rates</b>			
POLICYRATE	Central Bank Policy Rate	Bank for International Settlements	Natural logarithm
0.25	3-Month Treasury Bill	Reserve Bank of New Zealand	Natural logarithm
0.5	6-Month Treasury Bill	Reserve Bank of New Zealand	Natural logarithm
1	1-Year Treasury Rate	Reserve Bank of New Zealand	Natural logarithm
2	2-Year Treasury Rate	Reserve Bank of New Zealand	Natural logarithm
5	5-Year Treasury Rate	Reserve Bank of New Zealand	Natural logarithm
7	7-Year Treasury Rate	Reserve Bank of New Zealand	Natural logarithm
10	10-Year Treasury Rate	Reserve Bank of New Zealand	Natural logarithm
<b>Monetary Aggregates</b>			
M0	Monetary Base	Reserve Bank of New Zealand	Year-on-year growth rate
M1	Money Supply M1	OECD	Year-on-year growth rate
M3	Money Supply M3	Reserve Bank of New Zealand	Year-on-year growth rate
<b>Balance Sheet Assets</b>			
TA	Total Assets	Reserve Bank of New Zealand	First differences
TS	Total Securities Held Outright	Reserve Bank of New Zealand	First differences
DS	Debt Securities	Reserve Bank of New Zealand	First differences
<b>Balance Sheet Liabilities</b>			
CCY	Currency in Circulation	Reserve Bank of New Zealand	First differences
TR	Total Reserves	Reserve Bank of New Zealand	First differences
DD	Deposits of Depository Institutions	Reserve Bank of New Zealand	First differences
TL	Total Liabilities	Reserve Bank of New Zealand	First differences

## 5. United States

Variable	Description	Source	Transformation to induce stationarity
<b>Interest Rates</b>			
POLICYRATE	Central Bank Policy Rate	Bank for International Settlements	Natural logarithm
0.25	3-Month Treasury Bill	Federal Reserve Bank of St Louis	Natural logarithm
0.5	6-Month Treasury Bill	Federal Reserve Bank of St Louis	Natural logarithm
1	1-Year Treasury Rate	Federal Reserve Bank of St Louis	Natural logarithm
2	2-Year Treasury Rate	Federal Reserve Bank of St Louis	Natural logarithm
3	3-Year Treasury Rate	Federal Reserve Bank of St Louis	Natural logarithm
5	5-Year Treasury Rate	Federal Reserve Bank of St Louis	Natural logarithm
7	7-Year Treasury Rate	Federal Reserve Bank of St Louis	Natural logarithm
10	10-Year Treasury Rate	Federal Reserve Bank of St Louis	Natural logarithm
<b>Monetary Aggregates</b>			
M0	Monetary Base	Federal Reserve Bank of St Louis	Year-on-year growth rate
M1	Money Supply M1	OECD	Year-on-year growth rate
M2	Money Supply M2	Federal Reserve Bank of St Louis	Year-on-year growth rate
M3	Money Supply M3	OECD	Year-on-year growth rate
<b>Balance Sheet Assets</b>			
TA	Total Assets	Federal Reserve Bank of St Louis	First differences
TS	Total Securities Held Outright	Federal Reserve Bank of St Louis	First differences
DS	Debt Securities	Federal Reserve Bank of St Louis	First differences
<b>Balance Sheet Liabilities</b>			
CCY	Currency in Circulation	Federal Reserve Bank of St Louis	First differences
TR	Total Reserves	Federal Reserve Bank of St Louis	First differences
DD	Deposits of Depository Institutions	Federal Reserve Bank of St Louis	First differences
TL	Total Liabilities	Federal Reserve Bank of St Louis	First differences

## 6. Japan

Variable	Description	Source	Transformation to induce stationarity
<b>Interest Rates</b>			
POLICYRATE	Central Bank Policy Rate	Bank for International Settlements	Natural logarithm
0.25	3-Month Treasury Bill	Bank of Japan	Natural logarithm
0.5	6-Month Treasury Bill	Bank of Japan	Natural logarithm
1	1-Year Treasury Rate	Bank of Japan	Natural logarithm
2	2-Year Treasury Rate	Bank of Japan	Natural logarithm
3	3-Year Treasury Rate	Bank of Japan	Natural logarithm
5	5-Year Treasury Rate	Bank of Japan	Natural logarithm
7	7-Year Treasury Rate	Bank of Japan	Natural logarithm
10	10-Year Treasury Rate	Bank of Japan	Natural logarithm
<b>Monetary Aggregates</b>			
M0	Monetary Base	Bank of Japan	Year-on-year growth rate
M1	Money Supply M1	OECD	Year-on-year growth rate
M2	Money Supply M2	Bank of Japan	Year-on-year growth rate
M3	Money Supply M3	OECD	Year-on-year growth rate
<b>Balance Sheet Assets</b>			
TA	Total Assets	Bank of Japan	First differences
TS	Total Securities Held Outright	Bank of Japan	First differences
DS	Debt Securities	Bank of Japan	First differences
<b>Balance Sheet Liabilities</b>			
CCY	Currency in Circulation	Bank of Japan	First differences
TR	Total Reserves	Bank of Japan	First differences
DD	Deposits of Depository Institutions	Bank of Japan	First differences
TL	Total Liabilities	Bank of Japan	First differences

## 7. Euro-Area

Variable	Description	Source	Transformation to induce stationarity
<b>Interest Rates</b>			
POLICYRATE	Central Bank Policy Rate	Bank for International Settlements	Natural logarithm
0.25	3-Month Treasury Bill	European Central Bank	Natural logarithm
0.5	6-Month Treasury Bill	European Central Bank	Natural logarithm
1	1-Year Treasury Rate	European Central Bank	Natural logarithm
2	2-Year Treasury Rate	European Central Bank	Natural logarithm
3	3-Year Treasury Rate	European Central Bank	Natural logarithm
5	5-Year Treasury Rate	European Central Bank	Natural logarithm
7	7-Year Treasury Rate	European Central Bank	Natural logarithm
10	10-Year Treasury Rate	European Central Bank	Natural logarithm
<b>Monetary Aggregates</b>			
M0	Monetary Base	European Central Bank	Year-on-year growth rate
M1	Money Supply M1	OECD	Year-on-year growth rate
M2	Money Supply M2	European Central Bank	Year-on-year growth rate
M3	Money Supply M3	OECD	Year-on-year growth rate
<b>Balance Sheet Assets</b>			
TA	Total Assets	European Central Bank	First differences
TS	Total Securities Held Outright	European Central Bank	First differences
DS	Debt Securities	European Central Bank	First differences
<b>Balance Sheet Liabilities</b>			
CCY	Currency in Circulation	European Central Bank	First differences
TR	Total Reserves	European Central Bank	First differences
DD	Deposits of Depository Institutions	European Central Bank	First differences
TL	Total Liabilities	European Central Bank	First differences

## 8. Switzerland

Variable	Description	Source	Transformation to induce stationarity
<b>Interest Rates</b>			
POLICYRATE	Central Bank Policy Rate	Bank for International Settlements	Natural logarithm
0.25	3-Month Treasury Bill	Swiss National Bank	Natural logarithm
0.5	6-Month Treasury Bill	Swiss National Bank	Natural logarithm
1	1-Year Treasury Rate	Swiss National Bank	Natural logarithm
2	2-Year Treasury Rate	Swiss National Bank	Natural logarithm
3	3-Year Treasury Rate	Swiss National Bank	Natural logarithm
5	5-Year Treasury Rate	Swiss National Bank	Natural logarithm
7	7-Year Treasury Rate	Swiss National Bank	Natural logarithm
10	10-Year Treasury Rate	Swiss National Bank	Natural logarithm
<b>Monetary Aggregates</b>			
M0	Monetary Base	Swiss National Bank	Year-on-year growth rate
M1	Money Supply M1	Swiss National Bank	Year-on-year growth rate
M2	Money Supply M2	Swiss National Bank	Year-on-year growth rate
M3	Money Supply M3	Swiss National Bank	Year-on-year growth rate
<b>Balance Sheet Assets</b>			
TA	Total Assets	Swiss National Bank	First differences
TS	Total Securities Held Outright	Swiss National Bank	First differences
DS	Debt Securities	Swiss National Bank	First differences
<b>Balance Sheet Liabilities</b>			
CCY	Currency in Circulation	Swiss National Bank	First differences
TR	Total Reserves	Swiss National Bank	First differences
DD	Deposits of Depository Institutions	Swiss National Bank	First differences
TL	Total Liabilities	Swiss National Bank	First differences
