#### Abstract

In this paper we explore the relation between matrix measures and Quasi-Birth-and-Death processes. We derive an integral representation of the transition function in terms of a matrix valued spectral measure and corresponding orthogonal matrix polynomials. We characterize several stochastic properties of Quasi-Birth-and-Death processes by means of this matrix measure and illustrate the theoretical results by several examples.

AMS Subject Classification: 60J10, 42C05
Keywords and Phrases: Block tridiagonal infinitesimal generator, Quasi-Birth-and-Death processes, spectral measure, matrix measure, canonical moments.

## 1 Introduction

Let $\left(\Omega, \mathcal{F}, P,\left(X_{t}\right)_{t \geq 0}\right)$ be a continuous-time two-dimensional homogeneous Markov process with state space

$$
\begin{equation*}
E=\left\{(i, j) \in \mathbb{N}_{0} \times\{1, \ldots, d\}\right\}, d \in \mathbb{N}, d<\infty \tag{1.1}
\end{equation*}
$$

and infinitesimal generator

$$
Q=\left(Q_{i j}\right)_{i, j=0,1, \ldots}=\left(\begin{array}{cccccc}
B_{0} & A_{0} & & & & 0  \tag{1.2}\\
C_{1}^{T} & B_{1} & A_{1} & & & \\
& C_{2}^{T} & B_{2} & A_{2} & & \\
& & C_{3}^{T} & B_{3} & A_{3} & \\
0 & & & \ddots & \ddots & \ddots
\end{array}\right),
$$

where $A_{0}, A_{1}, \ldots, B_{0}, B_{1}, \ldots, C_{1}, C_{2}, \ldots \in \mathbb{R}^{d \times d}$. The transition rate from state $(i, j)$ to state $(k, \ell)$ is given by the element in the position $(j, \ell)$ of the matrix $Q_{i k}$. Markov processes with an infinitesimal generator matrix of the form (1.2) are known as continuous-time Quasi-Birth-and-Death processes. These models have many applications in the evaluation of communicating systems and queueing systems [see e.g. Neuts (1981), Ost (2001), Dayar and Quessette (2002)] and have been analyzed by many authors [see e.g. Bright and Taylor (1995), Ramaswami and Taylor (1996), Latouche, Pearce and Taylor (1998)]. The case $d=1$ corresponds to a "classical" Birth-and-Death process with a tridiagonal infinitesimal generator which has been investigated in great detail using the theory of orthogonal polynomials by Karlin and McGregor (1957, 1957a). Since this pioneering work several authors have used these techniques to derive interesting properties of Birth-and-Death processes in terms of orthogonal polynomials and the corresponding measure of orthogonality [see e.g. van Doorn (2002, 2003)].

It is the purpose of the present paper to extend some of these results to Quasi-Birth-and-Death processes with a generator of the form (1.2) using the theory of matrix measures and corresponding orthogonal matrix polynomials.
We associate to a matrix of the form (1.2) a sequence of matrix polynomials, recursively defined by

$$
\begin{equation*}
-x Q_{n}(x)=A_{n} Q_{n+1}(x)+B_{n} Q_{n}(x)+C_{n}^{T} Q_{n-1}(x) \tag{1.3}
\end{equation*}
$$

with initial conditions $Q_{-1}(x)=0$ and $Q_{0}(x)=I_{d}$. In Section 2 we formulate sufficient conditions on the infinitesimal generator (1.2) such that there exists a matrix measure $\Sigma$ on the real line with

$$
\left\langle Q_{i}, Q_{j}\right\rangle=\int_{\mathbb{R}} Q_{i}(x) d \Sigma(x) Q_{j}^{T}(x)=\delta_{i j} I_{d}
$$

i.e. the matrix polynomials are orthonormal with respect to the matrix measure $\Sigma$ [see Sinap and Van Assche (1996)]. In this case we derive an integral representation for the blocks of the transition function in terms of the orthogonal matrix polynomials $Q_{i}$ and the matrix measure $\Sigma$, which generalize the representation of Karlin and McGregor (1957) to the case $d>1$. We also investigate relations between the Stieltjes transforms of random walk measures corresponding to two Quasi-Birth-and-Death processes, where only a few blocks differ. In Section 3 we discuss several examples to illustrate the theory. Finally, in Section 4 the theoretical results are used
to characterize $\alpha$-recurrence of Quasi-Birth-and-Death processes [for a definition see van Doorn (2006)].

## 2 Quasi-Birth-and-Death processes and matrix polynomials

A matrix measure $\Sigma=\left\{\sigma_{i j}\right\}_{i, j=1, \ldots, d}$ on the real line is a function for which $\Sigma(A)=\left\{\sigma_{i j}(A)\right\}_{i, j=1, \ldots, d}$ is a symmetric and nonnegative definite matrix in $\mathbb{R}^{d \times d}$ for each Borel set $A \subset \mathbb{R}$, where the entries $\sigma_{i j}$ are finite signed measures. The moments of the matrix measure $\Sigma$ are defined by the $d \times d$ matrices

$$
S_{k}=\int x^{k} d \Sigma(x), \quad k=0,1, \ldots
$$

and throughout this paper we will only consider matrix measures with existing moments of all order. The 'left' inner product with respect to $\Sigma$ of two matrix polynomials $Q$ and $P$ is defined by

$$
\langle Q, P\rangle=\int Q(x) d \Sigma(x) P^{T}(x)
$$

If $\left\{S_{n}\right\}_{n \geq 0}$ is a sequence of matrices such that the block Hankel matrices

$$
\underline{H}_{2 m}=\left(\begin{array}{ccc}
S_{0} & \cdots & S_{m} \\
\vdots & & \vdots \\
S_{m} & \cdots & S_{2 m}
\end{array}\right), m \geq 0
$$

are positive definite, then there exists a matrix measure $\Sigma$ with moments $S_{n}, n \geq 0$, and a sequence of matrix polynomials $\left\{Q_{n}(x)\right\}_{n \geq 0}$ which is orthogonal with respect to $\Sigma$ [see Marcellán and Sansigre (1993)]. The following theorem characterizes the existence of a matrix measure $\Sigma$ such that there is a sequence of matrix polynomials which is orthogonal with respect to $\Sigma$. The proof follows by similar arguments as presented in Dette et al. (2006) and is therefore omitted.

Theorem 2.1 Let the matrices $A_{n}, n \geq 0$, and $C_{n}^{T}, n \geq 1$, in (1.2) be nonsingular and assume that $\left\{Q_{n}(x)\right\}_{n \geq 0}$ is a sequence of matrix polynomials defined by recursion (1.3).
There exists a matrix measure $\Sigma$ with positive definite block Hankel matrices $\underline{H}_{2 m}, m \geq 0$, such that the sequence of matrix polynomials $\left\{Q_{n}(x)\right\}_{n \geq 0}$ is orthogonal with respect to $\Sigma$ if and only if there is a sequence of nonsingular matrices $\left\{R_{n}\right\}_{n \geq 0}$ with

$$
\begin{align*}
& R_{n} B_{n} R_{n}^{-1} \text { symmetric } \forall n \in \mathbb{N}_{0}, \\
& R_{n}^{T} R_{n}=C_{n}^{-1} \cdots C_{1}^{-1}\left(R_{0}^{T} R_{0}\right) A_{0} \cdots A_{n-1} \quad \forall n \in \mathbb{N} . \tag{2.1}
\end{align*}
$$

Moreover,

$$
R_{0}^{-1}\left(\left(R_{0}^{T}\right)^{-1}\right)=\left(R_{0}^{T} R_{0}\right)^{-1}=S_{0}
$$

and the matrices $\left\{\tilde{R}_{n}\right\}_{n \geq 0}=\left\{U_{n} R_{n}\right\}_{n \geq 0}$, where $U_{n}, n \geq 0$, are orthogonal matrices, also satisfy condition (2.1).

If condition (2.1) is satisfied, the corresponding measure $\Sigma$ is called a spectral measure corresponding to $\left\{Q_{n}(x)\right\}_{n \geq 0}$ and $Q$, respectively. The infinitesimal generator matrix (1.2) is called conservative, if

$$
\left(A_{0}+B_{0}\right) \mathbf{1}=\mathbf{0},\left(A_{n}+B_{n}+C_{n}^{T}\right) \mathbf{1}=\mathbf{0} \quad \forall n \in \mathbb{N},
$$

where $\mathbf{1}=(1,1, \ldots, 1)^{T} \in \mathbb{R}^{d}$ and $\mathbf{0}=(0,0, \ldots, 0)^{T} \in \mathbb{R}^{d}$ [see Anderson (1991)]. In this case there exists a transition function

$$
\begin{equation*}
P(t)=\left(P_{i i^{\prime}}(t)\right)_{i, i^{\prime}=0,1, \ldots}, \tag{2.2}
\end{equation*}
$$

with $d \times d$ block matrices $P_{i i^{\prime}}(t) \in \mathbb{R}^{d \times d}$,

$$
P(0)=I \text { and } P^{\prime}(0)=Q,
$$

which satisfies the Kolmogorov forward differential equation

$$
\begin{equation*}
P^{\prime}(t)=P(t) Q \quad \forall t \geq 0 \tag{2.3}
\end{equation*}
$$

and the Kolmogorov backward differential equation

$$
P^{\prime}(t)=Q P(t) \quad \forall t \geq 0
$$

The probability $P\left(X_{t}=\left(i^{\prime}, j^{\prime}\right) \mid X_{0}=(i, j)\right)$ of going from state $(i, j)$ to $\left(i^{\prime}, j^{\prime}\right)$ in time $t$ is given by the element in the position $\left(j, j^{\prime}\right)$ of the matrix $P_{i i^{\prime}}(t)$.
The infinitesimal generator $Q$ is called regular, if there exists only one transition function (2.2) such that the Kolmogorov differential equations are satisfied [see Anderson (1991)]. Throughout this paper we will assume that there exists a transition function $P(t)$ such that the Kolmogorov forward differential equation (2.3) is satisfied. If additionally a spectral measure $\Sigma$ corresponding to the generator matrix (1.2) exists, we can derive an integral representation for the block of the transition function $P(t)$ in the position $(i, j)$ in terms of the spectral measure and the corresponding matrix orthogonal polynomials, which generalizes the famous Karlin and McGregor representation.

Theorem 2.2 Assume that the assumptions of Theorem 2.1 are satisfied and that there exists a transition function $P(t)$ which satisfies the Kolmogorov forward equation (2.3) for all $t \geq 0$. Then the following representation holds for the block $P_{i j}(t) \in \mathbb{R}^{d \times d}$ in the position $(i, j)$ of the transition function $P(t)$

$$
\begin{equation*}
P_{i j}(t)=\left(\int e^{-t x} Q_{i}(x) d \Sigma(x) Q_{j}^{T}(x)\right)\left(\int Q_{j}(x) d \Sigma(x) Q_{j}^{T}(x)\right)^{-1} . \tag{2.4}
\end{equation*}
$$

Proof. Let $Q(x)=\left(Q_{0}^{T}(x), Q_{1}^{T}(x), \ldots\right)^{T}$ denote the vector of orthogonal matrix polynomials $Q_{i}(x)$ with respect to the spectral measure $\Sigma$. Then the recursive relation (1.3) is equivalent to the matrix equation

$$
-x Q(x)=Q Q(x)
$$

Defining

$$
F(x, t):=P(t) Q(x)
$$

we obtain the differential equation

$$
\frac{d}{d t} F(x, t)=P^{\prime}(t) Q(x)=P(t) Q Q(x)=-x P(t) Q(x)=-x F(x, t)
$$

and the condition $P(0)=I$ yields

$$
F(x, 0)=P(0) Q(x)=Q(x) .
$$

Hence, it follows that

$$
F(x, t)=e^{-t x} Q(x)=P(t) Q(x)
$$

which implies (integrating with respect to $d \Sigma(x)$ )

$$
\int e^{-t x} Q(x) d \Sigma(x) Q_{j}^{T}(x)=P(t) \int Q(x) d \Sigma(x) Q_{j}^{T}(x) .
$$

Because of the orthogonality of the matrix polynomials $Q_{n}(x), n \geq 0$, we obtain for the blocks $P_{i j}(t)$ of the transition function the representation

$$
P_{i j}(t)=\left(\int e^{-t x} Q_{i}(x) d \Sigma(x) Q_{j}^{T}(x)\right)\left(\int Q_{j}(x) d \Sigma(x) Q_{j}^{T}(x)\right)^{-1}
$$

which completes the proof of Theorem 2.2.

In what follows we present two results, which relate the Stieltjes transforms of the spectral measures of two Quasi-Birth-and-Death processes, which have an infinitesimal generator of similar structure. The first result refers to the case where the entry $B_{0}$ has been replaced by the matrix $\bar{B}_{0}$. The proof is similar to a corresponding result in Dette et al. (2006) and is therefore omitted.

Theorem 2.3 Consider the infinitesimal generator defined by (1.2) and the matrix

$$
\bar{Q}=\left(\begin{array}{cccccc}
\bar{B}_{0} & A_{0} & & & & 0  \tag{2.5}\\
C_{1}^{T} & B_{1} & A_{1} & & & \\
& C_{2}^{T} & B_{2} & A_{2} & & \\
& & C_{3}^{T} & B_{3} & A_{3} & \\
0 & & & \ddots & \ddots & \ddots
\end{array}\right) .
$$

Let $\Sigma$ be a spectral measure corresponding to the infinitesimal generator $Q$ with positive definite block Hankel matrices such that the matrix $R_{0} \bar{B}_{0} R_{0}^{-1}$ is symmetric, and such that $\left\{R_{n}\right\}_{n \geq 0}$ is a sequence of matrix polynomials which satisfies condition (2.1). Then there exists a spectral measure $\bar{\Sigma}$ corresponding to $\bar{Q}$. If the spectral measures $\Sigma$ and $\bar{\Sigma}$ are determined by their moments, then the Stieltjes transforms of the measures satisfy

$$
\Phi(z)=\int \frac{d \Sigma(t)}{z-t}=\left\{\left(\int \frac{d \bar{\Sigma}(t)}{z-t}\right)^{-1}-S_{0}^{-1}\left(\bar{B}_{0}-B_{0}\right)\right\}^{-1} .
$$

Given a sequence $\left\{Q_{n}(x)\right\}_{n \geq 0}$ of matrix polynomials defined by recursion (1.3), the corresponding associated sequence of matrix polynomials $\left\{Q_{n}^{(k)}(x)\right\}_{n \geq 0}$ of order $k, k \geq 1$, is defined by a recursion of the form (1.3), in which the matrices $A_{n}, B_{n}$ and $C_{n}$ have been replaced by the matrices $A_{n+k}$, $B_{n+k}$ and $C_{n+k}$, respectively [see van Doorn (2006)]. The following result gives a relation between the Stieltjes transform of the spectral measure corresponding to the sequence of matrix polynomials $\left\{Q_{n}(x)\right\}_{n \geq 0}$ and the Stieltjes transform of the spectral measure corresponding to $\left\{Q_{n}^{(k)}(x)\right\}_{n \geq 0}$. The associated Quasi-Birth-and-Death process will be denoted by $\left(X_{t}^{(k)}\right)_{t \geq 0}$ with state space $E$ defined by equation (1.1) (throughout this paper we use the notation $X_{t}^{(0)}:=X_{t}$ ).

Theorem 2.4 Consider the infinitesimal generator $Q$ defined by (1.2) and the matrix

$$
Q^{(k)}=\left(\begin{array}{cccccc}
B_{k} & A_{k} & & & & 0 \\
C_{k+1}^{T} & B_{k+1} & A_{k+1} & & & \\
& C_{k+2}^{T} & B_{k+2} & A_{k+2} & & \\
& & C_{k+3}^{T} & B_{k+3} & A_{k+3} & \\
0 & & & \ddots & \ddots & \ddots
\end{array}\right) .
$$

The matrix $Q^{(k)}$ is called the associated matrix of order $k, k \geq 1$, corresponding to $Q$. Assume that $\Sigma$ is a spectral measure corresponding to $Q$ with positive definite block Hankel matrices, that is, there exists a sequence $\left\{R_{n}\right\}_{n \geq 0}$ of nonsingular matrices, which satisfies condition (2.1) of Theorem 2.1. Then there exists a spectral measure $\Sigma^{(k)}$ corresponding to $Q^{(k)}$ with positive
definite block Hankel matrices. If the measures are determined by their moments, then the Stieltjes transforms of the measures are related by

$$
\begin{aligned}
\int \frac{d \Sigma(x)}{z-x}= & R_{0}^{-1}\left\{z I_{d}-E_{0}-D_{1}\left\{z I_{d}-E_{1}-D_{2}\left\{z I_{d}-E_{2}-\ldots\right.\right.\right. \\
& \left.\ldots-D_{k-1}\left\{z I_{d}-E_{k-1}-D_{k} R_{k} \int \frac{d \Sigma^{(k)}(x)}{z-x} R_{k}^{T} D_{k}^{T}\right\}^{-1} D_{k-1}^{T}\right\}^{-1} \ldots \\
& \left.\left.\ldots D_{2}^{T}\right\}^{-1} D_{1}^{T}\right\}^{-1}\left(R_{0}^{T}\right)^{-1}
\end{aligned}
$$

where

$$
\begin{equation*}
D_{n+1}=-R_{n} A_{n} R_{n+1}^{-1}, \quad E_{n}=-R_{n} B_{n} R_{n}^{-1}, D_{n}^{T}=-R_{n} C_{n}^{T} R_{n-1}^{-1}, \tag{2.6}
\end{equation*}
$$

and the Stieltjes transforms of the matrix measures $\Sigma^{(k)}$ and $\Sigma^{(k+1)}$ are related by

$$
\int \frac{d \Sigma^{(k)}(x)}{z-x}=R_{k}^{-1}\left\{z I_{d}+R_{k} B_{k} R_{k}^{-1}-R_{k} A_{k} \int \frac{d \Sigma^{(k+1)}(x)}{z-x} R_{k+1}^{T} R_{k+1} C_{k+1}^{T} R_{k}^{-1}\right\}^{-1}\left(R_{k}^{T}\right)^{-1}
$$

Proof. Let the sequence of polynomials $\left\{Q_{n}(x)\right\}_{n \geq 0}$ be defined by recursion (1.3) with corresponding spectral measure $\Sigma$. Then the polynomials $W_{n}(x):=R_{n} Q_{n}(x)$ are orthonormal with respect to the matrix measure $\Sigma$ and satisfy the three term recurrence relation

$$
x W_{n}(x)=D_{n+1} W_{n+1}(x)+E_{n} W_{n}(x)+D_{n}^{T} W_{n-1}(x)
$$

with initial conditions $W_{-1}(x)=0$ and $W_{0}(x)=R_{0}$, where

$$
\begin{equation*}
D_{n+1}=-R_{n} A_{n} R_{n+1}^{-1}, \quad E_{n}=-R_{n} B_{n} R_{n}^{-1}, D_{n}^{T}=-R_{n} C_{n}^{T} R_{n-1}^{-1} . \tag{2.7}
\end{equation*}
$$

From Zygmunt (2002) it follows that

$$
\begin{align*}
\int \frac{d \Sigma(x)}{z-x}=\lim _{n \rightarrow \infty} & R_{0}^{-1}\left\{z I_{d}-E_{0}-D_{1}\left\{z I_{d}-E_{1}-D_{2}\left\{z I_{d}-E_{2}-\ldots\right.\right.\right.  \tag{2.8}\\
& \left.\left.\left.\left.\ldots-D_{n}\left\{z I_{d}-E_{n}\right\}^{-1} D_{n}^{T}\right\}^{-1} \cdots\right\}^{-1} D_{2}^{T}\right\}^{-1} D_{1}^{T}\right\}^{-1}\left(R_{0}^{T}\right)^{-1}
\end{align*}
$$

Assume that the sequence of polynomials $\left\{Q_{n}^{(k)}(x)\right\}_{n \geq 0}$ is defined by recursion (1.3), where the matrices $B_{n}, A_{n}$ and $C_{n}$ have been replaced by the matrices $B_{n+k}, A_{n+k}$ and $C_{n+k}$, respectively, that is

$$
-x Q_{n}^{(k)}(x)=A_{n+k} Q_{n+1}^{(k)}(x)+B_{n+k} Q_{n}^{(k)}(x)+C_{n+k}^{T} Q_{n-1}^{(k)}(x),
$$

with $Q_{0}^{(k)}(x)=I$ and $Q_{-1}^{(k)}(x)=0$. Define $A_{n}^{(k)}=A_{n+k}, B_{n}^{(k)}=B_{n+k}, C_{n}^{(k)}=C_{n+k}$ and $R_{n}^{(k)}=$ $R_{n+k}, n \geq 0$. From Theorem 2.1 we obtain the symmetry of the matrices

$$
-R_{n}^{(k)} B_{n}^{(k)}\left(R_{n}^{(k)}\right)^{-1}=-R_{n+k} B_{n+k} R_{n+k}^{-1} \quad \forall n \geq 0
$$

and the equation

$$
\begin{aligned}
\left(R_{n}^{(k)}\right)^{T} R_{n}^{(k)} & =R_{n+k}^{T} R_{n+k} \\
& =C_{n+k}^{-1} C_{n+k-1}^{-1} \cdots C_{k+1}^{-1} C_{k}^{-1} \cdots C_{1}^{-1} R_{0}^{T} R_{0} A_{0} A_{1} \cdots A_{k-1} A_{k} \cdots A_{n+k-1} \\
& =C_{n+k}^{-1} C_{n+k-1}^{-1} \cdots C_{k+1}^{-1} R_{k}^{T} R_{k} A_{k} \cdots A_{n+k-1} \\
& =\left(C_{n}^{(k)}\right)^{-1}\left(C_{n-1}^{(k)}\right)^{-1} \cdots\left(C_{1}^{(k)}\right)^{-1}\left(R_{0}^{(k)}\right)^{T} R_{0}^{(k)} A_{0}^{(k)} \cdots A_{n-1}^{(k)} \forall n \geq 1 .
\end{aligned}
$$

Therefore, from Theorem 2.1 it follows that there exists a spectral measure $\Sigma^{(k)}$ with positive definite block Hankel matrices corresponding to the sequence of polynomials $\left\{Q_{n}^{(k)}(x)\right\}_{n \geq 0}$. The polynomials $W_{n}^{(k)}(x):=R_{n}^{(k)} Q_{n}^{(k)}(x)$ are orthonormal with respect to the measure $\Sigma^{(k)}$ and satisfy the recursion

$$
x W_{n}^{(k)}(x)=D_{n+1}^{(k)} W_{n+1}^{(k)}(x)+E_{n}^{(k)} W_{n}^{(k)}(x)+\left(D_{n}^{(k)}\right)^{T} W_{n-1}^{(k)}(x), W_{0}^{(k)}(x)=R_{0}^{(k)}=R_{k},
$$

where

$$
D_{n+1}^{(k)}=D_{n+k+1}, E_{n}^{(k)}=E_{n+k} \quad \forall n \geq 0 .
$$

Therefore, it follows from Zygmunt (2002)

$$
\begin{aligned}
\int \frac{d \Sigma^{(k)}(x)}{z-x}= & \lim _{n \rightarrow \infty}\left(R_{0}^{(k)}\right)^{-1}\left\{z I_{d}-E_{0}^{(k)}-D_{1}^{(k)}\left\{z I_{d}-E_{1}^{(k)}-D_{2}^{(k)}\left\{z I_{d}-E_{2}^{(k)}-\ldots\right.\right.\right. \\
& \left.\left.\left.\left.\ldots-D_{n}^{(k)}\left\{z I_{d}-E_{n}^{(k)}\right\}^{-1}\left(D_{n}^{(k)}\right)^{T}\right\}^{-1} \ldots\right\}^{-1}\left(D_{2}^{(k)}\right)^{T}\right\}^{-1}\left(D_{1}^{(k)}\right)^{T}\right\}^{-1}\left(\left(R_{0}^{(k)}\right)^{T}\right)^{-1} \\
(2.9) \quad & \lim _{n \rightarrow \infty} R_{k}^{-1}\left\{z I_{d}-E_{k}-D_{k+1}\left\{z I_{d}-E_{k+1}-D_{k+2}\left\{z I_{d}-E_{k+2}-\ldots\right.\right.\right. \\
& \left.\left.\left.\left.\ldots-D_{n+k}\left\{z I_{d}-E_{n+k}\right\}^{-1} D_{n+k}^{T}\right\}^{-1} \ldots\right\}^{-1} D_{k+2}^{T}\right\}^{-1} D_{k+1}^{T}\right\}^{-1}\left(R_{k}^{T}\right)^{-1} .
\end{aligned}
$$

A combination of the equations (2.8) and (2.9) yields

$$
\begin{aligned}
\int \frac{d \Sigma(x)}{z-x}= & R_{0}^{-1}\left\{z I_{d}-E_{0}-D_{1}\left\{z I_{d}-E_{1}-D_{2}\left\{z I_{d}-E_{2}-\ldots\right.\right.\right. \\
& \left.\ldots-D_{k-1}\left\{z I_{d}-E_{k-1}-D_{k} R_{k} \int \frac{d \Sigma^{(k)}(x)}{z-x} R_{k}^{T} D_{k}^{T}\right\}^{-1} D_{k-1}^{T}\right\}^{-1} \ldots \\
& \left.\left.\ldots D_{2}^{T}\right\}^{-1} D_{1}^{T}\right\}^{-1}\left(R_{0}^{T}\right)^{-1}
\end{aligned}
$$

and from equations (2.9) and (2.7) we obtain

$$
\begin{aligned}
\int \frac{d \Sigma^{(k)}(x)}{z-x} & =R_{k}^{-1}\left\{z I_{d}-E_{k}-D_{k+1} R_{k+1} \int \frac{d \Sigma^{(k+1)}(x)}{z-x} R_{k+1}^{T} D_{k+1}^{T}\right\}^{-1}\left(R_{k}^{T}\right)^{-1} \\
& =R_{k}^{-1}\left\{z I_{d}+R_{k} B_{k} R_{k}^{-1}-R_{k} A_{k} \int \frac{d \Sigma^{(k+1)}(x)}{z-x} R_{k+1}^{T} R_{k+1} C_{k+1}^{T} R_{k}^{-1}\right\}^{-1}\left(R_{k}^{T}\right)^{-1}
\end{aligned}
$$

which completes the proof of the theorem.

Remark 2.5 Note that in the literature, many queueing models are considered, where the matrices $C_{n}$ do not have full rank [see Latouche and Ramaswami (1999)]. Following the arguments used in Remark 2.7 in Dette et al. (2006) the conditions

$$
\begin{aligned}
& R_{n} B_{n}=E_{n} R_{n}, n \geq 0 \\
& C_{n+1} R_{n+1}^{T} R_{n+1}=R_{n}^{T} R_{n} A_{n}, n \geq 1
\end{aligned}
$$

are sufficient for the existence of a spectral measure $\Sigma$ corresponding to $Q$, where $\left\{E_{n}\right\}_{n \geq 0}$ is a sequence of symmetric matrices and

$$
\int Q_{i}(x) d \Sigma(x) Q_{j}^{T}(x)=\delta_{i j} R_{j}^{T} R_{j}
$$

In other words: the assumption of nonsingularity of the matrices $C_{n}$ can be relaxed. The same arguments as used in Theorem 2.2 then imply

$$
P_{i j}(t) R_{j}^{T} R_{j}=\int e^{-t x} Q_{i}(x) d \Sigma(x) Q_{j}^{T}(x)
$$

## 3 Examples

Example 3.1 Dayar and Quessette (2002) considered a queuing system consisting of a $M / M / 1-$ system and a $M / M / 1 / d-1$-system. Both queues have Poisson arrival processes with rate $\lambda_{i}, i=$ 1,2 , and exponential service distributions with rate $\mu_{i}, i=1,2$, and it was assumed that $\gamma=$ $\lambda_{1}+\lambda_{2}+\mu_{1}+\mu_{2}$. This system can be described by a homogeneous Markov process $X(t)=$ $\left(L_{1}(t), L_{2}(t)\right)_{t \in \mathbb{R}^{+}}$with state space $E=\mathbb{N} \times\{0, \ldots, d-1\}$, where $L_{1}(t)$ and $L_{2}(t)$ denote the length of the first queue at time $t$ and the length of the second queue at time $t$, respectively. The entries of the corresponding infinitesimal generator (1.2) have the form

$$
\begin{gathered}
B_{0}=\left(\begin{array}{ccccc}
-\left(\lambda_{1}+\lambda_{2}\right) & \lambda_{2} & & & \\
\mu_{2} & -\left(\gamma-\mu_{1}\right) & \lambda_{2} & & \\
& \ddots & \ddots & \ddots & \\
& & \mu_{2} & -\left(\gamma-\mu_{1}\right) & \lambda_{2} \\
& & & \mu_{2} & -\left(\lambda_{1}+\mu_{2}\right)
\end{array}\right), \\
B_{i}=\left(\begin{array}{cccccc}
-\left(\gamma-\mu_{2}\right) & \lambda_{2} & & & \\
\mu_{2} & -\gamma & \lambda_{2} & & \\
& \ddots & \ddots & \ddots & \\
& & \mu_{2} & -\gamma & \lambda_{2} \\
& & & \mu_{2} & -\left(\gamma-\lambda_{2}\right)
\end{array}\right), i \geq 1,
\end{gathered}
$$

$A_{i}=\lambda_{1} I_{d}, i \geq 0$, and $C_{i}^{T}=\mu_{1} I_{d}, i \geq 1$. It is easy to see that $Q$ is conservative. A straightforward calculation shows that the conditions of Theorem 2.1 are satisfied with the matrices

$$
\begin{aligned}
& R_{0}=\operatorname{diag}\left(1, \sqrt{\frac{\lambda_{2}}{\mu_{2}}},\left(\sqrt{\frac{\lambda_{2}}{\mu_{2}}}\right)^{2}, \ldots,\left(\sqrt{\frac{\lambda_{2}}{\mu_{2}}}\right)^{d-1}\right) \\
& R_{i}=\left(\sqrt{\frac{\lambda_{1}}{\mu_{1}}}\right)^{i} R_{0}, i \in \mathbb{N} .
\end{aligned}
$$

This implies the existence of a spectral measure.
Example 3.2 Consider a homogeneous Markov process $\left(X_{t}\right)_{t \geq 0}$ with infinitesimal generator (1.2), where

$$
\begin{gathered}
B_{0}=\left(\begin{array}{ccccc}
-\gamma_{0} & \beta_{01} & & & \\
\beta_{10} & -\gamma_{1} & \beta_{12} & & \\
& \ddots & \ddots & \ddots & \\
& & \beta_{d-2, d-3} & -\gamma_{d-2} & \beta_{d-2, d-1} \\
& & & \beta_{d-1, d-2} & -\gamma_{d-1}
\end{array}\right), \gamma_{k} \neq 0, k=0, \ldots, d-1, \\
B_{i}=\left(\begin{array}{ccccc}
-\delta_{0} & \beta_{01} & \\
\beta_{10} & -\delta_{1} & \beta_{12} & \\
& \ddots & \ddots & \ddots & \\
& & \beta_{d-2, d-3} & -\delta_{d-2} & \beta_{d-2, d-1} \\
\beta_{d-1, d-2} & -\delta_{d-1}
\end{array}\right), i \geq 1, \delta_{k} \neq 0, k=0, \ldots, d-1,
\end{gathered}
$$

$A_{i}=\alpha_{1} I_{d}, i \geq 0$, and $C_{i}^{T}=\alpha_{2} I_{d}, i \geq 1$. A generator matrix of this form can be associated to a queueing model which consists of $d$ different $M / M / 1$-systems. Each $M / M / 1$-system has a Poisson arrival process with rate $\alpha_{1}$ and an exponential service time distribution with rate $\alpha_{2}$. If the model is situated in system $i$, then it changes to the system $i-1$ and $i+1$ with the rate $\beta_{i, i-1}$ and $\beta_{i, i+1}$, respectively. This model can be described by the two dimensional homogeneous Markov process $\left(N_{t}, S_{t}\right)_{t \geq 0}$ with state space $E=\mathbb{N}_{0} \times\{0, \ldots, d-1\}$, where $N_{t}$ denotes the number of customers in the whole model at time $t$ and $S_{t}$ denotes the number of the system at time $t$.
If $\beta_{i j} \neq 0$ for all $i, j=0, \ldots, d-1$, then the conditions of Theorem 2.1 are satisfied with

$$
\begin{equation*}
R_{0}=\operatorname{diag}\left(\sqrt{\frac{\beta_{d-1, d-2} \cdots \beta_{10}}{\beta_{01} \cdots \beta_{d-2, d-1}}}, \sqrt{\frac{\beta_{d-1, d-2} \cdots \beta_{21}}{\beta_{12} \cdots \beta_{d-2, d-1}}}, \ldots, \sqrt{\frac{\beta_{d-1, d-2}}{\beta_{d-2, d-1}}}, 1\right) \tag{3.1}
\end{equation*}
$$

and

$$
\begin{equation*}
R_{n}=\left(\sqrt{\frac{\alpha_{1}}{\alpha_{2}}}\right)^{n} R_{0}, n \geq 1 . \tag{3.2}
\end{equation*}
$$

This implies the existence of a spectral measure $\Sigma$ corresponding to $Q$.

Example 3.3 We now specify the situation of Example 3.2 to the case, where the parameters in the infinitesimal generator $Q$ satisfy

$$
\delta_{i}=: \delta, \gamma_{i}=: \gamma, \beta_{i, i+1}=: \beta_{1} \text { and } \beta_{i+1, i}=: \beta_{2} \forall i=0, \ldots, d-1, \beta_{1}, \beta_{2} \neq 0
$$

Then the matrices in (2.6) have the form

$$
\begin{gathered}
D:=D_{n}=-\sqrt{\alpha_{1} \alpha_{2}} I_{d}, n \geq 1, \\
E_{0}=\left(\begin{array}{ccccc}
\gamma & -\sqrt{\beta_{1} \beta_{2}} & & & \\
-\sqrt{\beta_{1} \beta_{2}} & \gamma & -\sqrt{\beta_{1} \beta_{2}} & & \\
& \ddots & \ddots & \ddots & \\
& & -\sqrt{\beta_{1} \beta_{2}} & \gamma & -\sqrt{\beta_{1} \beta_{2}} \\
& & & -\sqrt{\beta_{1} \beta_{2}} & \gamma
\end{array}\right)
\end{gathered}
$$

and

$$
E:=E_{n}=\left(\begin{array}{ccccc}
\delta & -\sqrt{\beta_{1} \beta_{2}} & & & \\
-\sqrt{\beta_{1} \beta_{2}} & \delta & -\sqrt{\beta_{1} \beta_{2}} & & \\
& \ddots & \ddots & \ddots & \\
& & -\sqrt{\beta_{1} \beta_{2}} & \delta & -\sqrt{\beta_{1} \beta_{2}} \\
& & & -\sqrt{\beta_{1} \beta_{2}} & \delta
\end{array}\right), n \geq 1 .
$$

The eigenvalues of the matrix $E$ are given by

$$
\lambda_{k}=\delta+2 \sqrt{\beta_{1} \beta_{2}} \cos \left(\frac{k \pi}{d+1}\right), k=1, \ldots, d
$$

with corresponding eigenvectors given by $u^{(k)}=\left(u_{1}^{(k)}, \ldots, u_{d}^{(k)}\right)^{T}$, where

$$
u_{j}^{(k)}=\sqrt{\frac{2}{d+1}} \sin \left(\frac{k j \pi}{d+1}\right), j, k=1, \ldots, d
$$

With the notation $H:=\operatorname{diag}\left(\lambda_{1}-z, \ldots, \lambda_{d}-z\right)$ and $U:=\left(u^{(1)}, \ldots, u^{(d)}\right)$, it follows that

$$
E-z I_{d}=U H U^{T} \text { and } U^{T} U=I_{d} .
$$

Let $\bar{Q}$ be the infinitesimal generator obtained from $Q$ by replacing the first diagonal block $B_{0}$ by the block $B_{1}$ (which coincides with all other blocks $B_{i}, i \geq 2$ ) and denote by $\bar{\Sigma}$ the spectral measure corresponding to $\bar{Q}$. From Duran (1999) we obtain for the Stieltjes transform $\bar{\Phi}(z)$ of the matrix measure $\bar{\Sigma}$

$$
\begin{aligned}
\bar{\Phi}(z) & =-\frac{1}{2} D^{-2}\left(E-z I_{d}\right)^{1 / 2}\left\{I_{d}+\left\{I_{d}-4 D^{2}\left(E-z I_{d}\right)^{-2}\right\}^{1 / 2}\right\}\left(E-z I_{d}\right)^{1 / 2} \\
& =-\frac{1}{2 \alpha_{1} \alpha_{2}} U H^{1 / 2}\left\{I_{d}+\left\{I_{d}-4 \alpha_{1} \alpha_{2} H^{-2}\right\}^{1 / 2}\right\} H^{1 / 2} U^{T}
\end{aligned}
$$

and Theorem 2.3 gives the Stieltjes transform $\Phi(z)$ of the measure $\Sigma$. Moreover, the results in Duran (1999) also show that the support of the spectral measure is given by

$$
\begin{aligned}
\operatorname{supp}(\Sigma) & =\left\{x \in \mathbb{R}: D^{-1 / 2}\left(x I_{d}-E\right) D^{-1 / 2} \quad \text { has an eigenvalue in }[-2,2]\right\} \\
& =\left[-2 \sqrt{\alpha_{1} \alpha_{2}}+\delta+2 \sqrt{\beta_{1} \beta_{2}} \cos \left(\frac{\pi d}{d+1}\right), 2 \sqrt{\alpha_{1} \alpha_{2}}+\delta+2 \sqrt{\beta_{1} \beta_{2}} \cos \left(\frac{\pi}{d+1}\right)\right]
\end{aligned}
$$

Note that $\operatorname{supp}(\Sigma) \subset[0, \infty)$ if $\delta \geq \alpha_{1}+\alpha_{2}+\beta_{1}+\beta_{2}$.

## $4 \quad \alpha$-recurrence

The decay parameter of continuous-time Quasi-Birth-and-Death processes was introduced by van Doorn (2006). To be precise assume that $\left(X_{t}\right)_{t \geq 0}$ is an irreducible Quasi-Birth-and-Death process with state space (1.1) and infinitesimal generator $Q$ defined by (1.2), where

$$
B_{0} \mathbf{1}+A_{0} \mathbf{1}<\mathbf{0} .
$$

Then the decay parameter $\alpha$ of the process $\left(X_{t}\right)_{t \geq 0}$, is defined by

$$
\alpha=\sup \left\{s \geq 0: e_{j}^{T} \int_{0}^{\infty} e^{s t} P_{i i^{\prime}}(t) d t e_{j^{\prime}}<\infty\right\}, \quad(i, j), \quad\left(i^{\prime}, j^{\prime}\right) \in E .
$$

The process $\left(X_{t}\right)_{t \geq 0}$ is called $\alpha$-recurrent if and only if for some state $(i, \ell) \in E$ (and then for all states in $E$ )

$$
\begin{equation*}
e_{\ell}^{T} \int_{0}^{\infty} e^{\alpha t} P_{i i}(t) d t e_{\ell}=\infty \tag{4.1}
\end{equation*}
$$

where $e_{\ell}=(0, \ldots, 0,1,0, \ldots, 0)^{T} \in \mathbb{R}^{d}$ denotes the $\ell$ th unit vector. The process $\left(X_{t}\right)_{t \geq 0}$ is called $\alpha$-positive if and only if for some state $(i, \ell) \in E$ (and then for all states in $E$ )

$$
\begin{equation*}
e_{\ell}^{T} \lim _{t \rightarrow \infty} e^{\alpha t} P_{i i}(t) e_{\ell}>0 \tag{4.2}
\end{equation*}
$$

The following results characterize $\alpha$-recurrence of the process $\left(X_{t}\right)_{t \geq 0}$ in terms of the spectral measure $\Sigma$, the corresponding orthogonal polynomials $Q_{j}(x)$ and the blocks of the infinitesimal generator. Throughout this section it will be assumed that condition (2.1) of Theorem 2.1 is satisfied.

Theorem 4.1 Assume that the conditions of Theorem 2.1 are satisfied with a spectral measure supported in the interval $[\alpha, \infty)$, and that there exists a transition function, which satisfies the

Kolmogorov forward differential equation (2.3). The process $\left(X_{t}\right)_{t \geq 0}$ is $\alpha$-recurrent if and only if for some state $(i, \ell) \in E$ (and then for all states in $E$ )

$$
\begin{equation*}
e_{\ell}^{T}\left(\int \frac{Q_{i}(x) d \Sigma(x) Q_{i}^{T}(x)}{x-\alpha}\right)\left(\int Q_{i}(x) d \Sigma(x) Q_{i}^{T}(x)\right)^{-1} e_{\ell}=\infty . \tag{4.3}
\end{equation*}
$$

Proof. With the representation (2.4) and Fubini's Theorem condition (4.1) is equivalent to

$$
e_{\ell}^{T}\left(\iint_{0}^{\infty} e^{(\alpha-x) t} d t Q_{i}(x) d \Sigma(x) Q_{i}^{T}(x)\right)\left(\int Q_{i}(x) d \Sigma(x) Q_{i}^{T}(x)\right)^{-1} e_{\ell}=\infty
$$

which implies (4.3).

In the following we define for a matrix measure $\Sigma$ with existing moments the $d \times d$ matrices $\zeta_{0}=0$ and $\zeta_{k}=\left(S_{k-1}-S_{k-1}^{-}\right)^{-1}\left(S_{k}-S_{k}^{-}\right) \in \mathbb{R}^{d \times d}$, where $S_{2 n}-S_{2 n}^{-}$and $S_{2 n-1}-S_{2 n-1}^{-}$denote the Schur complement of $S_{2 n}$ and $S_{2 n-1}$ in the matrix $\underline{H}_{2 n}$ and

$$
\underline{H}_{2 n-1}=\left(\begin{array}{ccc}
S_{1} & \cdots & S_{n} \\
\vdots & & \vdots \\
S_{n} & \cdots & S_{2 n-1}
\end{array}\right)
$$

respectively [see Dette und Studden (2002)]. The next result gives a representation of the Stieltjes transform of the spectral measure $\Sigma$ in terms of the quantities $\zeta_{j}$ and the blocks of the generator matrix (1.2).

Theorem 4.2 Assume that the conditions (2.1) of Theorem 2.1 are satisfied. Let $\left\{Q_{n}(x)\right\}_{n \geq 0}$ denote the corresponding orthogonal matrix polynomials defined by the recursion (1.3). Assume that the corresponding spectral measure $\Sigma$ is supported in the interval $[0, \infty)$ and that it is determined by its moments. Then the Stieltjes transform of the measure $\Sigma$ can be represented as

$$
\begin{aligned}
\int \frac{d \Sigma(x)}{z-x}=\lim _{n \rightarrow \infty} & \left\{z I_{d}-\left\{I_{d}-\left\{z I_{d}-\ldots\right.\right.\right. \\
& \left.\left.\left.\left.\ldots-\left\{z I_{d}-\zeta_{2 n+1}^{T}\right\}^{-1} \zeta_{2 n}^{T}\right\}^{-1} \cdots\right\}^{-1} \zeta_{2}^{T}\right\}^{-1} \zeta_{1}^{T}\right\}^{-1} S_{0}
\end{aligned}
$$

In particular, the following representations hold

$$
\begin{align*}
\int \frac{d \Sigma(x)}{x} & =\lim _{n \rightarrow \infty} \sum_{j=0}^{n+1}\left(\zeta_{2 j+1}^{T} \zeta_{2 j-1}^{T} \cdots \zeta_{1}^{T}\right)^{-1}\left(\zeta_{2 j}^{T} \zeta_{2 j-2}^{T} \cdots \zeta_{2}^{T}\right) S_{0}  \tag{4.4}\\
& =\lim _{n \rightarrow \infty} \sum_{j=0}^{n+1} T_{j+1}^{-1} A_{j}^{-1} C_{j}^{T} T_{j-1} T_{j}^{-1} A_{j-1}^{-1} C_{j-1}^{T} T_{j-2} T_{j-1}^{-1} \cdots T_{0} T_{1}^{-1} A_{0}^{-1} T_{0} S_{0} \tag{4.5}
\end{align*}
$$

where $T_{j}=Q_{j}(0), j \geq 0$.
Proof. From Dette and Studden (2002) it follows that the monic orthogonal matrix polynomials $\left\{\underline{P}_{n}(x)\right\}_{n \geq 0}$ with respect to a matrix measure $\Sigma$ supported in $[0, \infty)$ satisfy the recursive relation

$$
\begin{equation*}
x \underline{P}_{n}(x)=\underline{P}_{n+1}(x)+\left(\zeta_{2 n+1}^{T}+\zeta_{2 n}^{T}\right) \underline{P}_{n}(x)+\zeta_{2 n}^{T} \zeta_{2 n-1}^{T} \underline{P}_{n-1}(x), \tag{4.6}
\end{equation*}
$$

with $\underline{P}_{-1}(x)=0, \underline{P}_{0}(x)=I_{d}, \zeta_{0}=0$ and $\zeta_{k}=\left(S_{k-1}-S_{k-1}^{-}\right)^{-1}\left(S_{k}-S_{k}^{-}\right)$, where the matrices

$$
\Delta_{2 n}:=\left\langle\underline{P}_{n}, \underline{P}_{n}\right\rangle=\left(S_{0} \zeta_{1} \ldots \zeta_{2 n}\right)^{T}
$$

are positive definite. Then the polynomials

$$
P_{n}(x):=\Delta_{2 n}^{-1 / 2} \underline{P}_{n}(x), n \geq 0
$$

are orthonormal with respect to the matrix measure $\Sigma$ and satisfy the recursion

$$
x P_{n}(x)=A_{n+1} P_{n+1}(x)+B_{n} P_{n}(x)+A_{n}^{T} P_{n-1}(x)
$$

with $P_{-1}(x)=0, P_{0}(x)=S_{0}^{-1 / 2}$ and

$$
\begin{align*}
A_{n+1} & =\Delta_{2 n}^{-1 / 2} \Delta_{2 n+2}^{1 / 2}  \tag{4.7}\\
B_{n} & =\Delta_{2 n}^{-1 / 2}\left(\zeta_{2 n}^{T}+\zeta_{2 n+1}^{T}\right) \Delta_{2 n}^{1 / 2}  \tag{4.8}\\
A_{n}^{T} & =\Delta_{2 n}^{-1 / 2} \zeta_{2 n}^{T} \zeta_{2 n-1}^{T} \Delta_{2 n-2}^{1 / 2} \tag{4.9}
\end{align*}
$$

From Zygmunt (2002) it follows that
(4.10) $F_{n}(z)=\left(P_{n+1}(z)\right)^{-1} \tilde{P}_{n+1}^{(1)}(z)=S_{0}^{1 / 2}\left\{z I_{d}-B_{0}-A_{1}\left\{z I_{d}-B_{1}-A_{2}\left\{z I_{d}-B_{2}-\ldots\right.\right.\right.$

$$
\left.\left.\ldots-A_{n}\left\{z I_{d}-B_{n}\right\}^{-1} A_{n}^{T}\right\}^{-1} \ldots A_{1}^{T}\right\}^{-1} S_{0}^{1 / 2}
$$

where $\tilde{P}_{n}^{(1)}(z)$ denote the first associated polynomials for $P_{n}(z)$. An application of Markov's Theorem [see Duran (1996)], (4.7) - (4.9) and (4.10) now yields

$$
\begin{align*}
\int \frac{d \Sigma(x)}{z-x}= & \lim _{n \rightarrow \infty} F_{n}(z)  \tag{4.11}\\
= & \lim _{n \rightarrow \infty}\left\{z I_{d}-\zeta_{1}^{T}-\left\{z I_{d}-\zeta_{2}^{T}-\zeta_{3}^{T}-\left\{z I_{d}-\zeta_{4}^{T}-\zeta_{5}^{T} \ldots\right.\right.\right. \\
& \left.\left.\left.\ldots-\left\{z I_{d}-\zeta_{2 n}^{T}-\zeta_{2 n+1}^{T}\right\}^{-1} \zeta_{2 n}^{T} \zeta_{2 n-1}^{T}\right\}^{-1} \ldots \zeta_{4}^{T} \zeta_{3}^{T}\right\}^{-1} \zeta_{2}^{T} \zeta_{1}^{T}\right\}^{-1} S_{0} \\
= & \lim _{n \rightarrow \infty}\left\{z I_{d}-\left\{I_{d}-\left\{z I_{d}-\right.\right.\right. \\
& \left.\left.\left.\left.\ldots-\left\{z I_{d}-\zeta_{2 n+1}^{T}\right\}^{-1} \zeta_{2 n}^{T}\right\}^{-1} \cdots\right\}^{-1} \zeta_{2}^{T}\right\}^{-1} \zeta_{1}^{T}\right\}^{-1} S_{0}
\end{align*}
$$

If $z=0$, then we obtain from (4.11) and Fair (1971)

$$
\int \frac{d \Sigma(x)}{-x}=-\lim _{n \rightarrow \infty} \sum_{j=0}^{n+1} X_{j+1}^{-1} \zeta_{2 j}^{T} \zeta_{2 j-1}^{T} X_{j-1} X_{j}^{-1} \zeta_{2 j-2}^{T} \zeta_{2 j-3}^{T} X_{j-2} X_{j-1}^{-1} \cdots X_{1} X_{2}^{-1} \zeta_{2}^{T} S_{0}
$$

where $X_{0}=I_{d}, X_{1}=-\zeta_{1}^{T}$ and

$$
X_{n+1}=-\left(\zeta_{2 n+1}^{T}+\zeta_{2 n}^{T}\right) X_{n}-\zeta_{2 n}^{T} \zeta_{2 n-1}^{T} X_{n-1}, n \geq 1
$$

An induction argument yields $X_{n}=(-1)^{n} \zeta_{2 n-1}^{T} \zeta_{2 n-3}^{T} \cdots \zeta_{1}^{T}, n \geq 1$, and the first representation in (4.4) follows. For the second part we note that the polynomials $\underline{Q}_{n}(x):=(-1)^{n} A_{0} \cdots A_{n-1} Q_{n}(x)$, $n \geq 0$, have leading coefficient $I_{d}$ and because of (1.3) they satisfy the recursion

$$
\underline{Q}_{n+1}(x)=x \underline{Q}_{n}(x)+A_{0} \cdots A_{n-1} B_{n} A_{n-1}^{-1} \cdots A_{0}^{-1} \underline{Q}_{n}(x)-A_{0} \cdots A_{n-1} C_{n}^{T} A_{n-2}^{-1} \cdots A_{0}^{-1} \underline{Q}_{n-1}(x)
$$

A comparison with the polynomials $\underline{P}_{n}(x)$ in (4.6) now yields

$$
\begin{align*}
A_{0} \cdots A_{n-1} B_{n} A_{n-1}^{-1} \cdots A_{0}^{-1} & =-\left(\zeta_{2 n}^{T}+\zeta_{2 n+1}^{T}\right)  \tag{4.12}\\
A_{0} \cdots A_{n-1} C_{n}^{T} A_{n-2} \cdots A_{0} & =\zeta_{2 n}^{T} \zeta_{2 n-1}^{T} \tag{4.13}
\end{align*}
$$

Define $T_{n}:=Q_{n}(0), n \geq 0$. Then (4.12) and (4.13) imply

$$
T_{n}=A_{n-1}^{-1} \cdots A_{0}^{-1} \zeta_{2 n-1}^{T} \zeta_{2 n-3}^{T} \cdots \zeta_{1}^{T} \forall n \geq 0
$$

Therefore, we can define the polynomials $\hat{Q}_{n}(x):=T_{n}^{-1} Q_{n}(x)$. From (1.3) it follows that these polynomials satisfy the recurrence relation

$$
x \hat{Q}_{n}(x)=\hat{A}_{n} \hat{Q}_{n+1}(x)+\hat{B}_{n} \hat{Q}_{n}(x)+\hat{C}_{n}^{T} \hat{Q}_{n-1}(x)
$$

with

$$
\hat{A}_{n}=T_{n}^{-1} A_{n} T_{n+1}, \quad \hat{B}_{n}=T_{n}^{-1} B_{n} T_{n}, \quad \hat{C}_{n}^{T}=T_{n}^{-1} C_{n}^{T} T_{n-1}
$$

and $\hat{A}_{n}+\hat{B}_{n}+\hat{C}_{n}^{T}=0$. Consequently we obtain from (4.12) and (4.13) that

$$
\begin{aligned}
\hat{A}_{0} \cdots \hat{A}_{n-1} \hat{B}_{n} \hat{A}_{n-1}^{-1} \cdots \hat{A}_{0}^{-1} & =-\left(\zeta_{2 n}^{T}+\zeta_{2 n+1}^{T}\right), \\
\hat{A}_{0} \cdots \hat{A}_{n-1} \hat{C}_{n}^{T} \hat{A}_{n-2}^{-1} \cdots \hat{A}_{0}^{-1} & =\zeta_{2 n}^{T} \zeta_{2 n-1}^{T}
\end{aligned}
$$

and hence

$$
\begin{aligned}
\zeta_{2 n+1}^{T} & =\hat{A}_{0} \cdots \hat{A}_{n} \hat{A}_{n-1}^{-1} \cdots \hat{A}_{0}^{-1} \\
\zeta_{2 n}^{T} & =\hat{A}_{0} \cdots \hat{A}_{n-1} \hat{C}_{n}^{T} \hat{A}_{n-1}^{-1} \cdots \hat{A}_{0}^{-1}
\end{aligned}
$$

Equation (4.4) finally yields

$$
\begin{aligned}
\int \frac{d \Sigma(x)}{x} & =\lim _{n \rightarrow \infty} \sum_{j=0}^{n+1} \hat{A}_{j}^{-1} \hat{C}_{j}^{T} \hat{A}_{j-1}^{-1} \cdots \hat{A}_{1}^{-1} \hat{C}_{1}^{T} \hat{A}_{0}^{-1} S_{0} \\
& =\lim _{n \rightarrow \infty} \sum_{j=0}^{n+1} T_{j+1}^{-1} A_{j}^{-1} C_{j}^{T} T_{j-1} T_{j}^{-1} A_{j-1}^{-1} C_{j-1}^{T} T_{j-2} T_{j-1}^{-1} \cdots T_{0} T_{1}^{-1} A_{0}^{-1} T_{0} S_{0}
\end{aligned}
$$

which completes the proof of the Theorem.

In the following, the $\alpha$-recurrence condition will be represented in terms of properties of the spectral measure, the corresponding orthogonal matrix polynomials and the blocks of the infinitesimal generator (1.2). For this purpose, consider the process $\left(X_{t, \alpha}\right)_{t \geq 0}$ with state space $E$ defined in (1.1) and infinitesimal generator matrix

$$
Q_{\alpha}=\left(\begin{array}{cccccc}
B_{0, \alpha} & A_{0, \alpha} & & & & 0 \\
C_{1, \alpha}^{T} & B_{1, \alpha} & A_{1, \alpha} & & & \\
& C_{2, \alpha}^{T} & B_{2, \alpha} & A_{2, \alpha} & & \\
& & C_{3, \alpha}^{T} & B_{3, \alpha} & A_{3, \alpha} & \\
0 & & & \ddots & \ddots & \ddots
\end{array}\right),
$$

where

$$
\begin{aligned}
A_{n, \alpha} & :=Q_{n}^{-1}(\alpha) A_{n} Q_{n+1}(\alpha), n \geq 0 \\
B_{n, \alpha} & :=Q_{n}^{-1}(\alpha) B_{n} Q_{n}(\alpha), n \geq 0 \\
C_{n, \alpha}^{T} & :=Q_{n}^{-1}(\alpha) C_{n}^{T} Q_{n-1}(\alpha), n \geq 1
\end{aligned}
$$

The corresponding sequence $\left\{Q_{n, \alpha}(x)\right\}_{n \geq 0}$ of matrix polynomials satisfies the recurrence relation

$$
-x Q_{n, \alpha}(x)=A_{n+1, \alpha} Q_{n+1, \alpha}(x)+B_{n, \alpha} Q_{n, \alpha}(x)+C_{n, \alpha}^{T} Q_{n-1, \alpha}(x)
$$

with initial conditions $Q_{-1, \alpha}(x)=0, \quad Q_{0, \alpha}(x)=I_{d}$. If the conditions (2.1) of Theorem 2.1 are satisfied, then the matrix $Q_{\alpha}$ can be symmetrized with the matrices

$$
R_{n, \alpha}=R_{n} Q_{n}(\alpha), n \geq 0 .
$$

An induction argument shows the representation

$$
\begin{equation*}
Q_{n, \alpha}(x)=Q_{n}^{-1}(\alpha) Q_{n}(x+\alpha), n \geq 0 \tag{4.14}
\end{equation*}
$$

and therefore

$$
\int Q_{n, \alpha}(x) d \Sigma_{\alpha}(x) Q_{m, \alpha}^{T}(x)=0, n \neq m
$$

where the matrix measure $\Sigma_{\alpha}$ is defined by

$$
\Sigma_{\alpha}((0, x])=\Sigma((\alpha, \alpha+x]) .
$$

If representation (2.4) holds, it is easy to see that

$$
\begin{equation*}
e^{\alpha t} P_{00}(t)=\int e^{-t x} d \Sigma_{\alpha}(x) S_{0}^{-1} \tag{4.15}
\end{equation*}
$$

and the following remark is a consequence of Theorem 4.1.

Remark 4.3 Assume that the conditions of Theorem 4.1 are satisfied and that $\Sigma$ is a corresponding spectral measure supported in the interval $[\alpha, \infty)$. The process $\left(X_{t}\right)_{t \geq 0}$ is $\alpha$-recurrent if and only if

$$
e_{j}^{T} \int_{0}^{\infty} \frac{d \Sigma_{\alpha}(x)}{x} S_{0}^{-1} e_{j}=e_{j}^{T} \int_{\alpha}^{\infty} \frac{d \Sigma(x)}{x-\alpha} S_{0}^{-1} e_{j}=\infty
$$

for some $j \in\{1, \ldots, d\}$. The process is $\alpha$-positive, if

$$
e_{\ell}^{T} \lim _{t \rightarrow \infty} e^{\alpha t} P_{00}(t) e_{\ell}>0
$$

for some $\ell \in\{1, \ldots, d\}$. This is the case if and only if the measure $e_{\ell}^{T} d \Sigma(x) S_{0}^{-1} e_{\ell}$ has a jump in the point $x=\alpha$.

Theorem 4.4 Assume that the conditions of Theorem 2.1 are satisfied and that the corresponding matrix measure $\Sigma$ is supported in the interval $[\alpha, \infty)$ and determined by its moments. If a transition function $P(t)$ satisfying $P^{\prime}(t)=P(t) Q$ exists, then the process $\left(X_{t}\right)_{t \geq 0}$ is $\alpha$-recurrent if and only if for some state $(0, \ell) \in E$ (and then for all states in $(0, k) \in E$ )

$$
e_{\ell}^{T} \sum_{j=0}^{\infty} H_{j+1}^{-1} A_{j}^{-1} C_{j}^{T} H_{j-1} H_{j}^{-1} A_{j-1}^{-1} C_{j-1}^{T} H_{j-2} \cdots C_{1}^{T} H_{1}^{-1} A_{0}^{-1} H_{0} S_{0} e_{\ell}=\infty,
$$

where $H_{j}:=Q_{j}(\alpha), j \geq 0$.

Proof. Because condition (2.1) holds for the polynomials $\left\{Q_{n}(x)\right\}_{n \geq 0}$, this condition is also fulfilled for the polynomials $\left\{Q_{n, \alpha}\right\}_{n \geq 0}$ with $R_{n, \alpha}:=R_{n} Q_{n}(\alpha), n \geq 0$. From equation (4.14) it follows that $Q_{j, \alpha}(0)=I_{d}$ for all $j \geq 0$. Therefore we obtain with equation (4.5)

$$
\int \frac{d \Sigma_{\alpha}(x)}{x}=\sum_{j=0}^{\infty} A_{j, \alpha}^{-1} C_{j, \alpha}^{T} A_{j-1, \alpha}^{-1} C_{j-1, \alpha}^{T} \cdots C_{1, \alpha}^{T} A_{0, \alpha}^{-1} S_{0}
$$

From the representation $A_{j, \alpha}^{-1} C_{j, \alpha}^{T}=Q_{j+1}(\alpha) A_{j}^{-1} C_{j}^{T} Q_{j-1}(\alpha), j \geq 0$, it follows from Remark 4.3 that the state $(0, \ell)$ is $\alpha$-recurrent if and only if

$$
e_{\ell}^{T} \sum_{j=0}^{\infty} H_{j+1}^{-1} A_{j}^{-1} C_{j}^{T} H_{j-1} H_{j}^{-1} A_{j-1}^{-1} C_{j-1}^{T} H_{j-2} \cdots C_{1}^{T} H_{1}^{-1} A_{0}^{-1} H_{0} S_{0} e_{\ell}=\infty
$$

where $H_{j}=Q_{j}(\alpha), j \geq 0$.
Remark 4.5 Assume that the conditions of Theorem 4.4 are satisfied, and let $\Sigma^{(1)}$ be a spectral measure corresponding to the sequence of associated matrix polynomials $\left\{Q_{n}^{(1)}(x)\right\}_{n \geq 0}$.

1. The state $(0, \ell) \in E$ is $\alpha$-recurrent if and only if

$$
e_{\ell}^{T} \int \frac{d \Sigma(x)}{x-\alpha} S_{0}^{-1} e_{\ell}=e_{\ell}^{T}\left\{-\alpha I_{d}-B_{0}-A_{0} \int \frac{d \Sigma^{(1)}(x)}{x-\alpha} R_{1}^{T} R_{1} C_{1}^{T}\right\}^{-1} e_{\ell}=\infty
$$

2. The state $(0, \ell) \in E$ is $\alpha$-positive if and only if

$$
\begin{aligned}
e_{\ell}^{T} \lim _{t \rightarrow \infty} e^{\alpha t} P_{00}(t) e_{\ell} & =\lim _{z \rightarrow 0} z e_{\ell}^{T} \int \frac{d \Sigma(x)}{(z+\alpha)-x} S_{0}^{-1} e_{\ell} \\
& =e_{\ell}^{T} \lim _{z \rightarrow 0}\left\{\frac{z+\alpha}{z} I_{d}+\frac{1}{z}\left(B_{0}-A_{0} \int \frac{d \Sigma^{(1)}(x)}{(z+\alpha)-x} R_{1}^{T} R_{1} C_{1}^{T}\right)\right\}^{-1}>0 .
\end{aligned}
$$

Note that conditions (4.1) and (4.2) reduce to recurrence and positive recurrence, if $\alpha=0$. Therefore, with Theorem 4.2 we obtain the following conditions for recurrence and positive recurrence of a Quasi-Birth-and-Death process.

Corollary 4.6 Assume that the conditions of Theorem 2.1 are satisfied, that the corresponding matrix measure $\Sigma$ is supported in the interval $[0, \infty)$ and determined by its moments. If a transition function $P(t)$ satisfying $P^{\prime}(t)=P(t) Q$ exists, then the following statements hold.

1. The state $(i, \ell) \in E$ is recurrent if and only if

$$
\begin{equation*}
e_{\ell}^{T}\left(\int \frac{Q_{i}(x) d \Sigma(x) Q_{i}^{T}(x)}{x}\right)\left(\int Q_{i}(x) d \Sigma(x) Q_{i}^{T}(x)\right)^{-1} e_{\ell}=\infty, \tag{4.16}
\end{equation*}
$$

where $e_{\ell}=(0, \ldots, 0,1,0, \ldots, 0)^{T}$. In particular, the state $(0, \ell) \in E$ is recurrent if and only if

$$
e_{\ell}^{T} \int_{0}^{\infty} \frac{d \Sigma(x)}{x} S_{0}^{-1} e_{\ell}=\infty
$$

2. The state $(0, \ell)$ is recurrent if and only if

$$
e_{\ell}^{T} \sum_{j=0}^{\infty} T_{j+1}^{-1} A_{j}^{-1} C_{j}^{T} T_{j-1} T_{j}^{-1} A_{j-1}^{-1} C_{j-1}^{T} T_{j-2} T_{j-1}^{-1} \cdots T_{0} T_{1}^{-1} A_{0}^{-1} T_{0} S_{0} e_{\ell}=\infty
$$

with $T_{j}=Q_{j}(0), j \geq 0$.
3. The state $(0, \ell)$ is positive recurrent if and only if the matrix measure $e_{\ell}^{T} d \Sigma(x) S_{0}^{-1} e_{\ell}$ has a jump in the point $x=0$.

Remark 4.7 1. Let $\Sigma^{(1)}$ be a spectral measure supported in $[0, \infty)$ corresponding to the associated polynomials $\left\{Q_{n}^{(1)}(x)\right\}_{n \geq 0}$ introduced in Theorem 2.4. Then, a combination of Theorem 2.4 and Corollary 4.6 shows that the state $(0, \ell) \in E$ is recurrent if and only if

$$
\begin{aligned}
e_{\ell}^{T} \int \frac{d \Sigma(x)}{x} S_{0}^{-1} e_{\ell} & =-\lim _{z \rightarrow 0} e_{\ell}^{T} \int \frac{d \Sigma(x)}{z-x} R_{0}^{T} R_{0} e_{\ell} \\
& =e_{\ell}^{T}\left\{-B_{0}-A_{0} \int \frac{d \Sigma^{(1)}(x)}{x} R_{1}^{T} R_{1} C_{1}^{T}\right\}^{-1} e_{\ell}=\infty
\end{aligned}
$$

An induction argument shows that

$$
Q_{n}^{(1)}(x)=-\tilde{Q}_{n+1}^{(1)}(x) S_{0}^{-1} A_{0}, n \geq 0
$$

where $\tilde{Q}_{n}^{(1)}(x)$ are the first associated polynomials corresponding to $Q_{n}^{(1)}(x)$, and $Q_{n}^{(1)}(x)$ are the associated polynomials of order $k=1$ corresponding to $Q_{n}(x)$. Therefore it follows for the Stieltjes transform of the spectral measure corresponding to the associated orthogonal polynomials that

$$
\begin{aligned}
& \int \frac{d \Sigma^{(1)}(x)}{x}=\lim _{n \rightarrow \infty} \sum_{j=0}^{n+1} A_{0}^{-1} S_{0} Z_{j+1}^{-1} A_{j+1}^{-1} C_{j+1}^{T} Z_{j-1} Z_{j}^{-1} A_{j}^{-1} \cdots \\
& \cdots A_{2}^{-1} C_{2}^{T} Z_{1}^{-1} A_{1}^{-1} Z_{0}\left(R_{1}^{T} R_{1}\right)^{-1}
\end{aligned}
$$

where $Z_{j}:=\tilde{Q}_{j+1}^{(1)}(0)$.
2. A straightforward calculation yields

$$
e_{i}^{T} \Sigma(\{0\}) e_{j}=\lim _{z \rightarrow 0} z e_{i}^{T} \Phi(z) e_{j}
$$

From Theorem 2.4 it follows that the state $(0, \ell) \in E$ is positive recurrent, if the condition

$$
\begin{aligned}
e_{\ell}^{T} \lim _{t \rightarrow \infty} P_{00}(t) e_{\ell} & =e_{\ell}^{T} \lim _{z \rightarrow 0} z \int \frac{d \Sigma(x)}{z-x} S_{0}^{-1} e_{\ell} \\
& =e_{\ell}^{T} \lim _{z \rightarrow 0} z R_{0}^{-1}\left\{z I_{d}+R_{0} B_{0} R_{0}^{-1}-R_{0} A_{0} \int \frac{d \Sigma^{(1)}(x)}{z-x} R_{1}^{T} R_{1} C_{1}^{T} R_{0}^{-1}\right\}^{-1} R_{0} e_{\ell} \\
& =e_{\ell}^{T} \lim _{z \rightarrow 0}\left\{I_{d}+\frac{1}{z}\left(B_{0}-A_{0} \int \frac{d \Sigma^{(1)}(x)}{z-x} R_{1}^{T} R_{1} C_{1}^{T}\right\}^{-1} e_{\ell}>0\right.
\end{aligned}
$$

holds.
