* This study arises from the author's Ph.D. dissertation in the Department of Economics at the University of Warwick. I am indebted to my advisors Jeffery Round and John Whalley for their valuable suggestions and comments. Moreover I have benefited from discussions with Gernot Klepper. An early version of this paper has been presented at the 11th European Economic Association Congress in Istanbul (21-24 August, 1996). Financial support from the Economic Social Research Council is gratefully acknowledged. All errors are my responsibility.

ABSTRACT

The economic implications and the income distribution effects of the CU between Turkey and the EU have been studied by applying a general equilibrium model to the Turkish economy. The numerical results show that the CU is not trade diverting. Most importantly, urban (rural) groups are better (worse) off in the scenario with fixed wages, while urban (rural) groups are worse (better) off in the scenario with flexible wages. Despite the owners of basic skilled labour being better off than both the owners of skilled labour and the owners of capital, overall income inequality rises in the scenario with fixed wages, suggesting that analysis on income inequality based on the functional distribution of income and the full employment assumption (i.e. Stolper-Samuelson theorem), might be misleading. In addition, in the case of fixed real wages, the model predicts the creation of 148000 new jobs. Sensitivity analysis seems to support this overall conclusion.

1. Introduction

In December 1995, the European Parliament ratified the customs union (CU) agreement with Turkey for mining and industrial products, with the exception of the commodities subject to the Common Agricultural Policy (CAP). This preferential trade arrangement came into force in January 1996. Despite this, very few attempts have been made to analyse the economic implications of this agreement on Turkey (Harrison, *et al.* 1997;¹ Mercenier and Yeldan, 1997²), and none of them has examined the impact on employment, and the distribution of income.

Trade and income distribution, and trade and employment have become two important issues among economists, as most of the recent studies argue that

¹ By using a representative consumer AGE model, Harrison, *et al.* (1997) estimate that Turkey's welfare gain of the CU agreement with the EU is equal to 1.1% of 1990 Turkish GDP (2,861 Billions of 1990 Turkish lira). However, this result has been obtained under the assumption that the Turkish terms of trade for non-agricultural products with third countries rises by 4.2%. Harrison, *et al.* claim that, by the year 2001, Turkey will negotiate preferential trade agreements with third countries, with whom the EU has negotiated Association and Free Trade agreements. This assumption plays a key role in the estimate of the aggregate welfare gain. As Harrison, *et al.* (1997, pp. 866-867) put it: "Improved access to these markets results in a gain in Turkish welfare of 0.5%, which is the largest gain of all the components." However, the improved access has been extended to all non-member countries, whilst Turkish exports with the countries, which negotiated preferential access agreements with the EU, are less than one third of Turkish exports to all non-member states (United Nations, 1997).

² Mercenier and Yeldan (1997) use a representative agent multiregional intertemporal AGE model, with increasing returns to scale and imperfect competition, to show that the CU agreement with the EU is detrimental to Turkish welfare. They argue that this regional agreement would generate welfare gains to Turkish consumers if, and only if, full integration of the commodity market with nontariff barriers is achieved.

trade with poor countries is the main source of both the decline in employment (Katz and Murphy, 1992; Sachs and Shatz, 1994; Wood, 1994) and the increase in wage inequality (MacPherson and Stewart, 1990; Borjas, Freeman and Katz, 1991; Murphy and Welch, 1991; Borjas and Ramey, 1994; Wood, 1994; Sachs and Shatz, 1996) in industrialised regions.³ The latter studies employ PE techniques to show that trade liberalisation widens the gap between the wage of the skilled worker (the abundant factor) and the wage of the unskilled worker (the scarce factor).⁴ Similar results are obtained by McDougall and Tyers (1997), who use a multiregional AGE model to explore the impact of world trade “opening up” on factor price inequality within the developed countries. They also found that the wage-rental ratio declines in the developed countries, in accordance with the Stolper-Samuelson theorem, which states that with trade, aggregate welfare gains are accompanied by an income redistribution effect in favour of the factor which is intensively used in the production of the exportable good. However, it is

³ It must be stressed that other economists, such as Lawrence and Slaughter (1993), Krugman and Lawrence (1993) and Bound and Johnson (1992), argue that trade is not an important contributor of the increasingly unequal distribution of wages, and plays a minor role in the contraction of U.S. manufacturing output and employment registered in the eighties. They believe that technological change is the cause of these trends in U.S. economy. In contrast, Wood (1994) argues that technology is only a further plausible force to explain the rise in relative demand of skilled labour in developed countries, in particular in U.S.. In this study, technological change is not modelled.

⁴ As MacPherson and Stewart (1990) pointed out, the immediate policy impact of this finding would be a request for trade protection by trade unions. The same concern is shared by Bhagwati and Dehejia (1994).

generally accepted that a trade policy satisfies the Pareto criterion of optimality, if those who gain from the policy *can* fully compensate those who lose.

Turkey is a middle income developing country abundant of both basic educated workers (basic skilled workers) and workers with virtually no schooling, who are unemployable in the manufacturing sector (no-skilled workers).⁵ Since Turkey levies very high sectoral tariffs on goods imported from both the EU and the non member states, and since the European CAP is not part of the CU protocol, this preferential trading arrangement with the EU might favour a wage rise of the basic skilled workers relative to both the skilled workers, who are richer, and the no-skilled workers, who are poorer. As a result, the impact on inequality is ambiguous. In addition, the Stolper-Samuelson theorem enables one to determine the relationship which may exist between foreign trade and functional income distribution, but it cannot predict the effects on the size distribution of income, which depend upon the combined ownership structure of primary factors of production.⁶ In a recent study on the theory of income distribution, Atkinson (1996, p. 20) says:

⁵ In this study, 8 labour categories are distinguished in 3 skilled workers and 5 unskilled workers. In turn, the latter group is distinguished in 4 basic skilled workers and 1 no-skilled workers. The no-skilled workers are farmers, who are unemployable in modern manufacturing. Migration issues are not taken into account.

⁶ Adelman and Robinson (1989) provide a substantive discussion on these concepts.

"Statements about the distribution of national income between wages and profits, or about the relative wages of skilled and unskilled workers, do not tell us directly how the share of the top 20 per cent or the bottom 20 per cent is likely to have changed. The factor distribution is certainly part of the story, but it is only part, and the other links in the chain need to receive more attention."

Nowadays, households receive their income from different sources, including capital, in the form of interest and dividends. In this study, each household income group engages its own members in eight different labour activities, owns two different shares of capital factor of production, and is a recipient of part of the quota rents which originate from the VER agreements with the EU.⁷ As a result, the finding that trade widens (reduces) the wage gap between skilled and basic skilled workers in developed (developing) countries cannot be used to predict the impact on overall inequality. It seems that the issue of international trade and the size distribution of income has been neglected by trade theory

⁷ The European Commission and the Istanbul Textiles and Clothing Exporters Association (ITKIB) have agreed quantitative restrictions and price mechanisms for Turkish textiles in 1982 and for clothing categories in 1986. Since then, the VERs arrangements have been regularly renewed (GATT, 1994). The elimination of the VER on Turkish textiles and apparel exports is an important issue of the preferential trade arrangement agreed with the EU. The Turkish production of textiles and apparel comprises 13% of Turkey's industrial production, and their exports represent 38% of merchandise exports. Most of them are exported to the European market. Hence, the elimination of the VERs could have an important impact on the Turkish economy. Certainly, the quota rents on textiles and apparel accruing to the exporting firms, and transferred to households, would be annulled; although the output of these sectors would expand, affecting sectoral factor mobility, welfare and, as a consequence, the distribution of income. Also Harrison, *et al.* (1997) assume that Turkish exporters obtain improved access in textiles and apparel, which consists of an exogenous increase of the prices received by Turkish exporters to the EU on these goods. However, the quota rents are not annulled. Hence, they over-estimate the computed welfare gains.

mainly because it requires a general equilibrium framework where sectoral output, trade flows, prices, factor returns, factor inputs and households' income are all simultaneously determined. So I have built a single country AGE model which is able to trace such effects in a multi-sector, multi-labour, multi-household framework, to quantify in a GE setting the effects of the CU agreement with the EU upon the welfare of Turkish rural and urban households, and the functional and the size distribution of income in Turkey.⁸

As I have mentioned above, with regard to the issue of trade and employment, several studies show that the trade liberalisation process is the cause of the decline (increase) in manufacturing employment in industrialised (developing) countries (Wood, 1994). So it is important to examine what might be the impact of the CU agreement on Turkish employment. The technique employed follows Krugman's model of global trade, employment and wages (Krugman, 1995). Krugman uses a stylised numerical GE two-country model with two productive inputs, skilled labour and unskilled labour, and two goods, one exportable and one importable, to study the impact of trade on employment of an

⁸ The analysis of economic policies on income distribution with AGE models has a long tradition. Adelman and Robinson (1978) were pioneering in this regard, as they examined the impact of various policies affecting income distribution in Korea. Their model identifies 15 different categories of income recipients, classified according to their skills. However, the impact on the size distribution of income has been derived indirectly, by using the calculation on factor incomes and by assuming that the size distribution of income within each occupational group is represented by a lognormal distribution.

industrialised country in the case of rigid real wages. His model predicts a fairly large negative employment effect, in relation to the labour input used intensively in producing the importable good. Following Krugman (1995), the employment implications of the CU agreement on the Turkish economy have been examined under the assumption that real wages are constant. Since Turkish industries employ unskilled workers intensively in manufacturing exportable goods, the CU leads to a rise in Turkish employment, as one would expect from the Krugman model applied to a developing country. I estimate that the number of new jobs created is equal to almost 148000. As Turkish manufacturing industries expand, the demand of basic skilled production workers rises substantially, comprising 75% of the new jobs created.

The second important finding is that although the owners of basic skilled labour (the abundant factor) are better off than both the owners of skilled labour and the owners of capital (the scarce factors), the impact on inequality in Turkey is ambiguous: it increases in the scenario with fixed wages and declines in the scenario with flexible wages. This is due to the fall (rise) in both agricultural capital income and farmers' earnings in the scenario with fixed (flexible) wages, which brings about a substantial rise (decline) of inequality between urban and rural household groups. This suggests that the analysis of trade impact on the distribution of income, only carried out with models which define household

groups according to their functional role and under the full employment assumption, such as the Stolper-Samuelson model, might be misleading.

To measure the impact on welfare, I use the Hicksian equivalent variation, which is widely used in AGE literature. The results indicate that although Turkey's welfare gain is in aggregate equal to 1226-2750 billions of 1990 Turkish lira (470-1054 million US dollars), the welfare impact on most of individual households depends hugely on the assumption made for the labour market. In particular, several urban groups would suffer large welfare losses in the case of flexible wages.

The static single country AGE model for the Turkish economy presented in this study specifies 20 urban household groups and 19 rural household groups, disaggregated by income class groups. Factor inputs (8 different labour categories and 1 capital) are fully mobile among sectors. In addition, unlike the Krugman model where traded goods are homogenous, it is assumed that domestic products, imports and exports are imperfect substitutes, in order to capture the *cross-hauling* phenomenon. The model assumes perfect competition and constant returns to scale, and this is because the literature on trade liberalisation and income distribution, which I hope to contribute to, makes these assumptions. The intra-industry trade model used for this study adopts the consumption tax base definition of the VAT, as the effective VAT rates in Turkey are not uniform

among commodities. The multiregional relations have been described in the form of two trade flows, one with the EU and one with the Rest of the World (RoW). To measure inequality, the income received by household members, adjusted by the households' "true" cost of living index, has been employed as a unit of measure.

The study also consists of a further four sections. Section 2 defines the algebraic specification of the model, and the measures of welfare and income inequality. Section 3 describes the benchmark. Section 4 explores the effects of the policy simulations, and the final section provides some conclusions.

2. Model specification

The trade model presented in this study is a standard static multi-sector, multi-labour, multi-household AGE model for Turkey with perfect competition and constant returns to scale. It is characterised by intra-industry trade as each tradeable commodity is exchanged in five different markets: the domestic market; the markets for imports from the EU, and the RoW; and the markets for export to the EU, and the RoW. This implies that although Turkey is assumed to be a price taker of international goods, domestic prices are endogenously determined. To

simplify the presentation, the specification of the model is divided into five components: production technology and factor demand, treatment of traded goods and foreign sector closure, household revenues and consumption, government revenues and consumption, and treatment of savings and investment decisions. In addition, the welfare and the income distribution measures have been reported. The complete algebraic formulation of the model is shown in Appendix A.

[2.1] Technology and factor demand

The production technology is described by a three stage nested separable CES function. At the first stage, sectoral production is generated as a Leontief function between raw-material inputs, which are assumed to be strictly complementary, and the value added, which is, at the second stage, a CES combination of three factor inputs, such as composite skilled labour, composite unskilled labour and capital. At the final stage, composite skilled labour and composite unskilled labour are respectively a CES aggregation of different skilled occupational categories and of different unskilled occupational categories.

The demand for factor inputs is derived by solving a two stage dual problem. Firstly, the minimisation of the skilled (unskilled) labour cost function subject to the skilled (unskilled) labour aggregation function yields the demand of

labour for different skilled (unskilled) occupational categories. Secondly, the minimisation of the total cost function subject to the production technology yields the demand for composite skilled labour, for composite unskilled labour and for capital. In other words, producers behave competitively and the factor returns equal their marginal revenue product.

It is assumed that factor inputs are mobile between sectors. Total labour demand of each category is equal to exogenous labour supply of each category only when wages are flexible, whereas total capital demand always equates exogenous aggregate capital. In addition, since Turkish farmers are virtually without schooling, they are unemployable in manufacturing. Or to put it in another way, since 95% of employed persons in Turkish agriculture are self-employed or unpaid family labour (Bulutay, 1995), it is assumed that any effect of the trade policy is perceived on farmers' wages.

[2.2] Treatment of traded goods and foreign sector closure

[2.2.1] Imports

As far as the imports are concerned, on the supply side, the *small country* assumption is postulated with respect to both regions. Hence, the import supply

functions are represented by the import price equations for the EU (pm_j^{EU}) and the RoW (pm_j^{RoW}) commodities:

$$(1) \quad pm_j^{EU} = \overline{pwm}_j^{EU} (1 + tm_j^{EU}),$$

$$(2) \quad pm_j^{RoW} = \overline{pwm}_j^{RoW} (1 + tm_j^{RoW}),$$

where \overline{pwm}_j^{EU} and \overline{pwm}_j^{RoW} are the fixed world prices of similar imports produced by the EU and the RoW, respectively; and tm_j^{EU} and tm_j^{RoW} are the effective *ad valorem* regional import tariff rates, gross of the effective *ad valorem* Mass Housing Fund levies on EU and RoW commodities evaluated in terms of tariff equivalent.⁹

On the import demand side, a two stage nested separable CES function is employed. Thus, it is assumed that buyers first decide between domestically produced goods and the composite imported commodities, and then choose between imports from the EU (M_j^{EU}) and imports from the RoW (M_j^{RoW}) with elasticity of substitution μ_j , according to the Armington specification (Armington, 1969), which states that products of different countries competing in the same market are imperfect substitutes:

⁹ Turkey has levied this surcharge on imports since 1984, the year of the Housing Fund law approved by the Turkish Parliament to finance the government's low cost housing scheme for poor and middle-class income households. The Mass Housing Fund duty will be phased out in 1998 (GATT, 1994).

$$(3) \quad M_j^{EU} = A_j^{\mu_j-1} \alpha_j^{\mu_j} \left(\frac{pm_j^{EU}}{pm_j^C} \right)^{-\mu_j} M_j^C,$$

$$(4) \quad M_j^{RoW} = A_j^{\mu_j-1} (1 - \alpha_j)^{\mu_j} \left(\frac{pm_j^{RoW}}{pm_j^C} \right)^{-\mu_j} M_j^C,$$

where M_j^C denotes the composite imports, pm_j^C is the composite domestic price of imports, A_j and α_j are the shift and the share parameters of the CES import aggregation function.

[2.2.2] Exports and VERs

With regard to exports, on the demand side, the *small country* assumption implies the export demand functions to both regions to be infinitely elastic. Hence, the Turkish export production is totally absorbed by foreign trade partners at world prices. However, for goods subject to VERs, the domestic supply price of exports (pe_i^{EU}) is endogenously determined by the amount of output which is agreed to be exported. Hence,

$$(5) \quad pe_i^{EU} = \frac{\overline{pwe}_i^{EU}}{1 + qr_i^{EU}},$$

where \overline{pwe}_i^{EU} is the fixed price of exports prevailing in the EU market, and qr_i^{EU} represents the *ad valorem* export quota premium parameter on Turkish textiles and apparel. When qr_i^{EU} is zero, the domestic supply price of exports to the EU is equal to the price prevailing in the EU market.

On the supply side, the export supply functions to the EU (E_i^{EU}) and the RoW (E_i^{RoW}) are derived by maximising total export sale revenues subject to the export possibility frontier (E_i^C), which is defined by a constant elasticity of transformation (CET) function. Hence,

$$(6) \quad E_i^{EU} = B_i^{-1} \left[\beta_i + \beta_i^{\eta_i+1} (1 - \beta_i)^{-\eta_i} \left(\frac{pe_i^{EU}}{\overline{pwe}_i^{RoW}} \right)^{-(\eta_i+1)} \right]^{-\left(\frac{\eta_i}{\eta_i+1}\right)} E_i^C,$$

$$(7) \quad E_i^{RoW} = B_i^{-1} \left[(1 - \beta_i) + \beta_i^{-\eta_i} (1 - \beta_i)^{\eta_i+1} \left(\frac{\overline{pwe}_i^{RoW}}{pe_i^{EU}} \right)^{-(\eta_i+1)} \right]^{-\left(\frac{\eta_i}{\eta_i+1}\right)} E_i^C,$$

where \overline{pwe}_i^{RoW} is the fixed price of exports prevailing in the RoW market, η_i the elasticity of transformation, B_i and β_i the shift and the share parameters of the CET export aggregation function. The composite export, E_i^C , is in turn derived by maximising total sales (domestic sales, plus export sales) subject to the production possibility frontier, which is a transformation function of the domestic good and the composite export with constant elasticity.

The rents from VERs (VER_i^{EU}), which are allocated to the Turkish exporting sectors,¹⁰ and then transferred to households, are proportional to the agreed quota premium and the level of exports:

$$(8) \quad VER_i^{EU} = qr_i^{EU} pe_i^{EU} E_i^{EU}.$$

When qr_i^{EU} is zero, quota rents disappear.

[4.2.2.3] Foreign sector closure

The current account deficit, \overline{CA} , is exogenously specified. Thus, the equilibrium in the balance of payments is:

$$(9) \quad \sum_i \overline{pwe}_i^{EU} E_i^{EU} + \sum_i \overline{pwe}_i^{RoW} E_i^{RoW} + \overline{CA} = \sum_j \overline{pwm}_j^{EU} M_j^{EU} + \sum_j \overline{pwm}_j^{RoW} M_j^{RoW}.$$

¹⁰ Since the Turkish government does not officially recognise any quota restriction, VERs agreements could only be made with Turkish industry associations (GATT, 1994). Thus, the rents from VERs accrued to the exporting firms which were able to obtain the export quota documents for deliveries to the EU.

[2.3] Households' revenues and consumption

[2.3.1] Households' revenues

The household sector comprises 20 urban and 19 rural household groups classified according to their income size. This disaggregation allows one to identify the losers and the gainers of the CU agreement between Turkey and the EU. The source of private income (HR_h) originates from wage payments, returns to capital, plus rents from VERs:

$$(10) \quad HR_h = \sum_c \zeta_{hc}^L \sum_i w_c L_{ic} + \zeta_h^{agr} \sum_{agr} rAK_{agr} + \zeta_h^{nagr} \left(\sum_{nagr} rAK_{nagr} + \sum_i VER_i^{EU} \right),$$

where $i = agr \cup nagr$, AK_{agr} and AK_{nagr} denote the net capital factor in agricultural and non-agricultural activities, respectively; L_{ic} represents the different labour categories employed in sector i ; r and w_c are the returns on capital and labours of different skills' categories, respectively; ζ_{hc}^L represents the distributive share parameters of labour income to households; and ζ_h^{agr} and ζ_h^{nagr} represent the distributive share parameters of agricultural and non-agricultural capital incomes to households, respectively. Since the Turkish government did not take part in the VERs arrangements with the EU, the rents accrued directly to

the private companies, which then distributed them back to shareholders in the form of dividends, and therefore in proportion to ζ_h^{nagr} .

[2.3.2] Households' consumption

Since the model is static, the households' utility functions are defined only over composite commodities. The households' consumption behaviour is obtained by maximising their utility functions, subject to their disposable income after deduction of savings, which are simply measured by the product between the average propensity to save and households' disposable income. Because of lack of data on the values of the elasticity of substitution among commodities for each household group, consumers' preferences have been described simply by Cobb-Douglas utility functions.¹¹

[2.4] Government revenues and expenditure

The government levies various taxes in order to finance its expenditures: a direct tax on household income; duties on imported goods; and indirect taxes on goods

¹¹ Harrison, *et al.* (1997) employs a CES utility function for their model with a representative consumer. The elasticity of substitution is also assumed *ad hoc*, and equal to 1.5.

and services. Despite the VAT system only being introduced in Turkey in 1985, VAT has become the main component of indirect tax revenues. AGE modellers usually levy the VAT rates on wage payments, plus the return to capital net of depreciation, thus assuming a proportionate tax on the value added by the firm (income tax base definition of the VAT).¹² However, by definition, VAT applies to commodities' sales net of all intermediate goods purchases (consumption tax base definition of the VAT). The consumption tax base definition of VAT is an equivalent concept of the income tax base definition only if the tax rate is uniform among commodities. However, the effective VAT rates in Turkey are commodity specific.¹³ Hence, the consumption tax base definition of the indirect taxes has been employed as replacement tax to perform a revenue neutral tariff reform. A fuel consumption tax is also considered.

With regard to the apportionment of customs' revenues to Turkey, it is assumed that these revenues are distributed to the members of the EU in proportion to their imports from the RoW (Corden, 1984). Thus, the duties on RoW imports collected by Turkey continue to be considered revenues of the Turkish government after the CU agreement.

¹²Harrison, *et al.* (1997) for example employ the VAT, defined on the income side, as a replacement tax to examine the impact of the CU agreement on Turkey's welfare.

¹³ The VAT system has been introduced in Turkey in 1985. As has been reported by the OECD (1992, 1995), the tax administration is still inadequate in the face of a large underground economy. Hence, despite the general VAT rate being 12% in 1990, the effective VAT rate is not uniform among commodities.

Public expenditure is simply treated as exogenous transfers to households and foreign institutions, and exogenous consumption of public goods and services in real terms. Thus, the government is a separate consuming agent; however its consumption decisions are not affected by price changes.

[2.5] Savings and investment decisions

Since the purpose of the model is to measure the static effects of the preferential trade arrangements with the EU, savings and investment decisions have been treated in a simple fashion. Households' savings are a constant proportion of disposable income; foreign savings, given by the current account deficit, are set exogenously; the budget deficit is exogenously specified as a difference between public revenues and exogenous public expenditure; capital depreciation is also assumed to be exogenous. Aggregate savings always equates aggregate investment, set exogenously in the model. Investment spending in each sector is held constant in real terms.

[2.6] Welfare and inequality measures

Two main indices are constructed to measure welfare changes in AGE literature: the equivalent variation and the compensating variation. Since they are very similar concepts, I use the Hicksian equivalent variation to study the impact of the partial trade liberalisation policy on each household income group. The welfare of urban and rural household income groups, and of the Turkish nation as a whole, is an additive aggregation of the welfare of each household income group.¹⁴

As far as the measurement of inequality is concerned, the study focuses on the inequality between urban and rural household members. The number of members within each household group varies substantially, and many of them are concentrated around the bottom and middle of the income distribution. This implies that considerable information would be lost if the income received by household income groups is used as a unit to measure inequality.¹⁵ Since the data source does not provide any additional information concerning the income

¹⁴ Although this procedure is widely used in cost-benefit analysis, it presents problems related to interpersonal utility comparisons, which are described in Boadway (1974). However, if one accepts the Pareto criterion of optimality, the aggregation is admissible. A more general discussion can be found in Hammond (1991).

¹⁵ Assume that there are two households groups (1 urban household group and 1 rural household group), each earning the same income. Obviously, income is equally distributed among household groups. Assume now that the rural household group is composed of k members. In this case, income would be unequally distributed among household members. This implies that the use of the income received by household groups as a unit of measure of inequality would be imprecise.

redistribution among household members in each income class group, the arithmetic mean income across household members in each income class group (hr_h) has been employed to examine the CU impact on the size distribution of income. However, income does not capture directly the price effect as tariffs fall. Therefore, the ratio between hr_h and the “true” cost of living index, $P_h = \prod_j (p_j / \vartheta_{jh})^{\vartheta_{jh}}$ where ϑ_{jh} denotes the household budget share for good j , (that is, the indirect utility function) is used as a basis to measure inequality.¹⁶

A set of general entropy indices for discrete distributions (GE_θ) has been employed to measure inequality. Given the assumption that, within each income class group, members receive the same income, GE_θ can be written as:

$$(11) \quad GE_\theta = \frac{1}{\theta^2 - \theta} \left[\frac{1}{K} \sum_{h=1}^H \left(\frac{k_h hr_h / P_h}{hr^m} \right)^\theta - 1 \right], \quad K = \sum_{h=1}^H k_h,$$

where k_h represents the number of household members in each household income group h ; K the total number of members; hr^m the arithmetic mean income across household members for the entire population in real terms; H the number of households income groups, which is 39 (i.e. 20 urban and 19 rural household income groups); and θ an arbitrary parameter which in principle can assume any

¹⁶ It must be stressed that household income does not adjust for differences in needs between households (so called *equivalisation* process), but only for the number of individuals (so called *reweighting* process). A fuller discussion on these issues can be found in Cowell (1984), Danziger and Taussig (1979), and Glewwe (1991).

real value, although particular values generate known inequality measures as specific cases. The generalised entropy index measures the average distance between each person's real actual income and the real income he would receive in a perfectly equal society. The advantage of this is that one can derive the inequality measure directly, without postulating the existence of a social welfare function, and discussing its desired properties (Cowell, 1995). The generalised entropy index has also been chosen as an indicator of income inequality because it has three main important properties: it satisfies the strong principle of transfer, according to which the change in inequality depends only on the "distance" between individual income shares, no matter which individuals one chooses; it is additively decomposable by population subgroups; and it encompasses all other measures that are ordinally equivalent: the entire subfamily of Atkinson indices ($\theta < 1$), the Theil index ($\theta = 1$) and half of the square of the coefficient of variation ($\theta = 2$).¹⁷ The additive decomposability property is very important for this study because one can compare the inter group income inequality among rural and urban areas and the inter group income inequalities among household members partitioned according to their geographical location.¹⁸

¹⁷ For proof and further discussion see Bourguignon (1979), Cowell (1980), Cowell and Kuga (1981a, 1981b), Shorrocks (1980).

¹⁸ Appendix B describes the measurement of inequality in more detail.

3. Features and properties of the benchmark

The benchmark for this study is mainly based upon the SAM for Turkey constructed for the year 1990 by the author in collaboration with Ozhan (De Santis and Ozhan, 1995 and 1997). The main feature of this SAM is that it incorporates information from household income and consumption expenditures survey as well as from household labour survey. However, this SAM does not provide information regarding regional trade data disaggregation. Thus, further sources have been used, such as a recent unpublished document of the State Institute of Statistics of Turkey (SIS), which shows the Turkish trade flows with the EU for the year 1990, and a recent unpublished dissertation by Kose (1995), who reports the import duties and the Mass Housing Fund duties, both disaggregated at regional level and consistent with the aggregate data published in the official Input-Output table for Turkey (SIS, 1994).

Table 1 shows a schematic representation of a SAM used for this study. Its main features are that firstly, the trade flows of Turkey are distinguished in two geographical directions: one with the EU and one with the RoW; and secondly, the rents on exports subject to the VERs are an income source of the factors of production accruing to the exporting firms. These aggregate accounts are disaggregated as follows: factor labour is disaggregated into 8 different types of

labour categories;¹⁹ households are disaggregated according to their income size and to their geographical regions (20 rural and 19 urban households); activities and commodities are disaggregated into 20 different types and classified according to the I-O table classification.²⁰ The accounts for imports and exports are disaggregated to model the relations with the EU and the RoW.²¹

The 1990 SAM for Turkey defines the cost of labour in terms of wages and salaries in line with the official Input-Output table for Turkey. In other words, it includes only the cost of employees. This implies that sectors, such as agriculture, dominated by self-employed and unpaid family labour, would be characterised by an underestimated ratio between labour and capital.

¹⁹ Partly following Wood (1994), I classify professional workers, managerial workers and clerical workers as the skilled labour group, with post-basic education; sales workers, service workers, non-agricultural workers and other workers as the unskilled labour group, with basic education; and the agricultural workers as the no skilled labour group, with virtually no schooling.

²⁰ The disaggregated 1990 SAM for Turkey comprises 54 sectors. Since the formation of CU between Turkey and the EU involves only mining and manufacturing commodities, the author has mainly aggregated the sectors subject to the CAP, mining and services. Mining has been aggregated mainly because it is a very small sector in terms of share in the GDP, labour force employed and volume of trade.

²¹ The EU is composed of 15 countries: 12 members existing in 1990, plus the new members Finland, Austria and Sweden.

Since self-employed and unpaid family labour comprise almost 95% of the employed persons in Turkish agriculture (Bulutay, 1995), and since this might effect the computation of the impact of the CU agreement on the size and the functional distribution of income, I have calculated the total farmers' earnings in Turkish agriculture for the year 1990, by using as a basis the average nominal wage in agriculture estimated by Bulutay for the year 1989 (Bulutay, 1995).²² According to my estimates for agriculture, the ratio between farmers' earnings and value added is 45.01%, and the ratio between total labour cost and value added is 48.09%. In the SAM, these two ratios are respectively equal to 7.06% and 10.13% (see Table 2).

Table 3 shows the statistics related to Turkish production and cost structure.

Table 4 shows the official statistics related to the composition of demand and trade flows with the EU.

Tables 5 and 6 show the source of income of urban and rural households, disaggregated by their income size and split in twentieth percentiles. Each income class group contains a large number of household members.

²² I have also considered the fact that the index of prices received by farmers increased by 62.8% from 1989 to 1990 (SPO, 1996), and that the full time equivalent work in agriculture is 41% of the entire time, as it has been estimated for similar European countries, such as Greece (EC, 1996).

D_j , E_j and M_j are evaluated in billions of Turkish lira. So, in this Table, they indicate the volumes of domestic sales, exports and imports gross of tariffs, respectively.

In aggregate, the geographical subgroups are composed of about 25 million urban household members and almost 28 million rural household members. It is evident that much of the urban and rural population is concentrated in the bottom-middle of the income distribution.

Source: Data elaboration from SIS (1994) and from an unpublished document of SIS.

In fact, 87.7% of urban household members (almost 22 millions) and 91.2% or rural household members (almost 25 millions) earn an income level below the

47.4% of the population. This implies that intra group income inequality as well as inter group income inequality are important features of Turkey. It is also interesting to note, for the subsequent numerical analysis on income inequality, that the main income source of rural households is agricultural labour and capital incomes. A contraction (expansion) in agriculture would imply a fall (rise) in rural welfare and a rise (fall) in inter group income inequality.

Table 7 and 8 show the partition of consumption expenditures among households.

Table 9 shows the *ad valorem* effective indirect tax rates on goods and services, the *ad valorem* effective duties levied on foreign imports, the quota premium and the European common external tariff. It is evident that the sectors which are much more protected by an effective tariff are beverages and tobacco, wearing apparel, footwear, wood and wood products, petroleum and coal products, non metallic mineral products and transport equipment. One might expect that these sectors are those which would be much more affected by the CU with the EU. The *ad valorem* effective net indirect tax rates (t_j) have been derived from De Santis and Ozhan (1995).

The duties levied by the EU on Turkish commodities and the European common external tariff are published by the Commission of the European Communities on an annual base (CEC, 1990). The duties levied by the EU on Turkish goods are zero. Since the EU imports a large number of differentiated commodities from non-member countries, which are subject to a large range of different duties, the

mode has been employed in this study as the average European common external tariff (cet_j^{RoW}). With regard to the quota restriction on Turkish textiles and wearing apparel exports to the EU, the exogenous increase on the export price of these goods, used by Harrison, *et al.* (1997), is assumed to be the *ad valorem* quota premium on VERs (qr_j^{EU}).

It is important to note for the subsequent analysis on welfare that the European common external tariff rates are lower than the tariff rates levied on Turkish imports from the RoW, with the only exemption of mining, wearing apparel and metal products. This implies that the CU should not be trade diverting.

With regard to the elasticity values, the factor substitution elasticities, the Armington trade elasticities, and the elasticities of transformation have been selected from Harrison, *et al.* (1992), and some of them have been adjusted for differences in sectoral aggregation (see Table 10). In addition, because of the lack of data, the elasticities of substitution among skilled and unskilled labour categories are assumed to be equal to 2 and 5, respectively.

<i>Other services</i>	2.010	2.000	5	2.9	5

σ_j : elasticity of substitution among primary factors of production; ε_j : elasticity of substitution between imported and domestically produced goods; μ_j : elasticity of substitution among imports from different regions; ρ_j : elasticity of transformation between production for exports and the domestic market; ϖ_j : elasticity of transformation among exports to different regions.

With regard to the calibration of all other parameter values, such as initial prices, direct tax rates on household income, marginal propensities to save, factor income distribution shares, shift and share parameters of different functional

forms, the standard techniques widely used in AGE literature are employed (Mansur and Whalley, 1984).

4. The revenue-neutral tariff reform scenarios

The preferential trading arrangement between Turkey and the EU is a regional economic integration agreement, signed in respect of the GATT's rules, according to which the member countries remove tariffs and quotas on mining and manufacturing commodities which circulate within the CU, and apply a common external tariff on these commodities from outside the CU. As a result, nominal protection rates on goods subject to the European CAP (that is, agricultural and food processed commodities) remain unchanged.

The indirect tax rate has been used as a policy instrument manoeuvrable by policy-makers to perform a revenue-neutral tariff reform. This experiment has been carried out under two different assumptions: firstly, real wages are assumed to be rigid (with the exception of farmers' wages), which implies that the effects of trade are manifested in changes in employment; and, secondly, real wages are assumed to be flexible and full employment is maintained.

Table 11 The impact on output and exports (Base year = 100)

<i>Leysperes Quantity Index</i>	101.7	116.6	108.4	100.7	114.2	109.1

Tables 11-13 report the economic impact of policy scenarios upon sectoral output, value added, and trade flows in Turkey. Tables 14-16 show the

consequences on welfare and the distribution of income among Turkish urban and rural households. Finally, Table 17 shows the impact on Turkish employment.

It is evident from Table 11 that the partial trade liberalisation policy favours a positive re-allocation of resources in Turkey: aggregate output, measured by the Leysperes quantity index, increases by 0.7%-1.7%. The major growing sectors are food processed products, beverages and tobacco, textiles (in the scenario with fixed wages), apparel (in the scenario with flexible wages), leather and fur products, footwear, chemical and non-metallic mineral products. These are the sectors where Turkey faces a comparative advantage and is in a position to compete with foreign countries, in particular with the European member states.²³ Despite the elimination of the VER in textiles towards the EU market, this sector might contract (i.e. scenario with flexible wages), if it is easy to switch sales from markets which are not constrained from VERs; and this has been postulated in this model by assuming a large elasticity of transformation among goods exported towards the EU and the RoW. In contrast, apparel rises in the flexible wages case, and contracts in the fixed wage case. The explanation used for textiles is also valid for apparel. However, apparel exports towards the

²³ In support of this finding, it is important to consider a study by Celasun (1994), which measures the revealed comparative advantage (RCA) for 26 Turkish industries for the period 1987-89. This study shows that the sectors having a positive RCA value are textiles-clothing-shoes, furniture, ceramic-glass, food-beverage-tobacco, rubber-plastic, petrol refineries, and iron-steel.

previously restricted EU market expand to the detriment of exports to non EU countries for two further reasons: firstly, the European common external tariff rate in apparel is larger than the tariff rate levied on Turkish apparel imports from the non member states; and secondly, the domestic demand in apparel is now satisfied by a large increase of apparel imports from the EU, which were previously protected by a huge effective tariff. The commodities which are favoured by the trade policy are industrial products to the detriment of services. Agriculture might contract as it is still heavily protected.²⁴

Table 12 The impact on the value added (Base year = 100)

	Fixed wages	Flexible wages
GDP in real terms	100.9	100.5
- Agriculture	94.6	102.5
- Industry	105.4	104.1
- Services	99.1	96.8

²⁴ In the future, the liberalisation of the European CAP and the enlargement of the CU agreement to agricultural commodities might favour the expansion of Turkish agriculture.

In fact, the value added in industry increases by 4.1%-5.4%; whilst the value added in agriculture increases by 2.5% in the scenario with flexible wages, but decreases by 5.4% in the scenario with fixed wages (see Table 12). In aggregate, GDP rises by 0.5%-0.9% in real terms. Hence, as a first finding, despite the aggregate impact on GDP being modest, the value added breakdown clearly shows that resources are reallocated favouring a remarkable expansion of the Turkish industrial sectors.

Table 13 reports the impact on trade flows. The partial trade liberalisation policy in favour of the EU increases the trade budget deficit with the EU by 5.1%-38%, and raises the aggregate trade volume with respect to the GDP by almost 10%. The impact of the CU on the import volume from the EU and the RoW is an indicator of the Vinerian trade creation and trade diversion effects. The volume of imports from both regions rises, and this implies that the CU agreement is not trade diverting. The latter outcome is due to the fact that Turkish tariffs levied on goods imported from non-member states are bigger than the European common external tariffs in most commodities (see Table 9).

Also the volume of exports is positively affected by the trade policy rising by 11.9%-13%. In particular, industrial exports increase by almost 25%, especially toward the EU, thanks to the elimination of VERs in textiles and wearing apparel. So, in summary, Tables 11-13 indicate that the regional

agreement with the EU leads to an enormous re-allocation of resources in favour of manufacturing industries, expands trade volume and is not trade diverting.

Table 13 The impact on the trade flows (Base year = 100)

	Fixed wages	Flexible wages

Table 14 reports the Hicksian equivalent variation for urban and rural household income groups and the aggregate measures of welfare. The positive sign indicates an improvement for the household in question. The Hicksian equivalent variation indices are measured as a percentage of household income. It is clear that as a consequence of the CU agreement, aggregate welfare for the nation as a whole rises, supporting the view that the preferential trading agreement with the EU is not trade diverting. In aggregate, the static welfare gains in Turkey are modest, as are typically found in most of AGE models with perfect competition and constant returns to scale, dealing with trade liberalisation issues. As a percentage of household income, they range between 0.4% in the case of flexible wages and 0.8% in the case of fixed wages. Namely, they range between 1226 and 2750 billions of 1990 Turkish lira (470-1054 million US dollars).²⁵

The results on welfare become more attractive when the welfare impact is decomposed among urban and rural household income groups. In the scenario with flexible wages, the urban household groups suffer an aggregate welfare loss of 2135 billions of 1990 Turkish lira, whereas rural households gain 3361 billions of 1990 Turkish lira. The opposite outcome is obtained in the scenario with fixed wages. However, in this case, rural household groups suffer a negligible welfare

²⁵ The average conversion factor for 1990 is an estimate of the IMF: 2608.6 Turkish Lira for 1 US dollar (IMF, 1995).

loss in aggregate. In summary, although the preferential trading agreement with the EU is not trade diverting, the welfare effects vary across the household groups, and according to the assumptions postulated for the labour market; the CU is potentially Pareto superior; and the welfare gains would be larger, and would benefit a greater number of household groups, if policy-makers encourage institutions to bargain a wage rate such that the real wages remain constant.

The impact on the size distribution of income, and the impact on the functional distribution of income, are shown in Tables 15 and 16. The first important finding is that the impact on overall inequality decreases in the full employment case in line with the Stolper-Samuelson theorem, but increases in the scenario with fixed wages. The second striking result is that that main source of inequality worsening (improving) is a large negative (positive) impact on the inter-group inequality among urban and rural household groups. It rises (decreases) by 6.5%-7.5% (10.3%-17.7%). These two different outcomes depend upon the performance of agricultural activities. In the scenario with fixed (flexible) wages, agriculture contracts (expands), thus reducing (increasing) agricultural capital and labour incomes (see Table 11), which are the main components of the private income in rural areas (see Table 6).

Table 15 The impact on the size distribution of income
(Base year = 100)

Generalised Entropy Index	Inequality	Fixed wages	Flexible wages
- 1	Overall inequality	100.5	98.0
	Within urban areas	99.9	98.2
	Within rural areas	99.7	100.7
	Between rural-urban areas	107.5	82.3
0	Overall inequality	100.7	98.2
	Within urban areas	100.3	98.8
	Within rural areas	100.1	100.4
	Between rural-urban areas	107.4	82.5
+ 1	Overall inequality	101.5	98.2
	Within urban areas	101.0	99.5
	Within rural areas	100.7	99.9
	Between rural urban areas	106.5	89.7
+ 2	Overall inequality	103.6	97.8
	Within urban areas	102.7	100.4
	Within rural areas	101.7	98.8
	Between rural-urban areas	107.3	82.7

It is important to emphasise the robustness of these results, which are independent of the choice upon the parameter θ used to estimate the generalised entropy indices. It must be stressed that measures with positive value of θ are particular sensitive to income differences at the top end of the income

distribution, whilst measures with negative value of θ are more sensitive to very low income. This explains why the inequality within groups varies with θ .

Table 16 The impact on the functional distribution of income
(Base year = 100)

	Fixed wages	Flexible wages
A -Capital income	100.7	99.1
- Agricultural income	97.2	103.7
- Non-agricultural income	101.5	98.1
B - Labour income	100.4	99.9
B.1 - Skilled labour income	100.6	98.2
- Professional workers	100.3	97.9
- Managerial workers	101.5	99.0
- Clerical workers	100.6	98.2
B.2 - Basic skilled labour income	101.8	99.5
- Sales workers	101.2	98.5
- Service workers	100.2	99.0
- Non agricultural workers	102.4	99.7
- Other workers	102.1	99.4
B.3 - No-skilled labour income	97.4	103.2
- Agricultural workers	97.4	103.2
<i>Basic skilled / Skilled labour income</i>	<i>101.2</i>	<i>101.3</i>
<i>No-skilled / Skilled labour income</i>	<i>96.8</i>	<i>105.2</i>
<i>Basic skilled labour / Capital income</i>	<i>101.1</i>	<i>100.4</i>
<i>No-skilled labour / Capital income</i>	<i>96.7</i>	<i>104.2</i>

When the analysis on the income distribution effect is carried out by examining the impact on the functional distribution of income, the results clearly indicate that in the scenario with flexible wages, the four ratios between (i) basic skilled and skilled labour incomes, (ii) no-skilled and skilled labour incomes, (iii) basic skilled labour and capital incomes, (iv) no-skilled labour and capital incomes, increase in line with the Stolper-Samuelson theorem, thus favouring a more equal distribution of income (see Table 16). In contrast, in the scenario with fixed wages, agricultural workers are worse off, thus leading to a rise in inequality. From the policy making point of view, it is very important to know what the effects of trade policies on income distribution are. The computed data for Turkey indicate that, despite the validity of the Stolper-Samuelson theorem, overall income inequality might increase with trade. As a result, the analysis of the trade impact on income distribution based on simplified two-sector, two-factors models, which define household groups according to their functional role, and under the assumption of full employment, might be misleading.

Table 17 reports the results concerning the impact of the CU agreement on Turkish employment, when real wages are constant. The only exception is the treatment of the agricultural category. Since agriculture in Turkey is a family-based activity, it is assumed that any effect of the trade policy is perceived on wages. The rigid real wages lead to an expansion of the aggregate labour demand

by 1%, which implies that almost 148000 new jobs are created, as a consequence of the CU agreement. In the rigid real wage case, efficiency gains are not absorbed by wage increases but rather by employment creation.²⁶ It is interesting to note that, as a consequence of the trade policy, 75% of new jobs concern basic skilled non-agricultural workers, who are demanded by the growing manufacturing industries.

Table 17 The impact on employment

	Relative change (Base year = 100)	Number of new workers	Share
Labour Input	101.0	147505	1.000
- Professional workers	100.3	2827	0.019
- Managerial workers	101.5	4901	0.033
- Clerical workers	100.6	5255	0.036
- Sales workers	101.2	18606	0.126
- Service workers	100.2	3050	0.021
- Agricultural workers	100.0	0	0.000
- Non agricultural workers	102.4	110251	0.747
- Other workers	102.1	2615	0.018

²⁶ A similar result has been obtained by Mercenier (1995) in examining the impact of the European single market in 1992 on employment among the EU member states.

This finding is in line with the Krugman (1995) model if applied to a developing country, and with Wood's results, according to which the cumulative demand for labour in manufacturing from 1985 to 1990 is increased by about 23 million in developing countries (Wood, 1994).

It is important to stress that, given the ex-ante large tariff rates (see Table 9), these results are obtained if the indirect tax rates used to perform a revenue-neutral tariff reform are uniformly increased by 55.8% in the case of fixed real wages, and by 57.6% in the case of flexible real wages. In other words, the standard VAT rate should rise from 12% (the prevailing rate in Turkey in 1990) to 18.7%-18.9%, which is reasonably close to the standard VAT rate applied in most of the European member states.

To evaluate the robustness of the above results, sensitivity analysis on the elasticity values has been carried out. All elasticities employed in this study have been divided by a factor of two in order to simulate the effects of the CU on a more rigid economy, and multiplied by a factor of two in order to consider the case of a more flexible economy. The results reported in Appendix C clearly show that the direction of the variable changes is robust, however their precise size depends upon the value of the elasticities. Some variation in the individual sectoral impact also exists. In the case of flexible wages, Turkey's welfare gains range between 75 (less flexible economy) and 4124 (more flexible economy)

billions of 1990 Turkish lira, and the change in income inequality between rural and urban groups measured by the Theil index ($\theta = 1$) ranges between - 8.5% (less flexible economy) and 0.6% (more flexible economy). In the case of fixed real wages, Turkey's welfare gains range between 1406 (less flexible economy) and 8433 (more flexible economy) billions of 1990 Turkish lira, and the change in inequality between groups ranges between 7.9% (less flexible economy) and 15.3% (more flexible economy). The impact on employment ranges between 86000 (less flexible economy) and 432000 (more flexible economy) new jobs. Similar gaps exist for all other statistics estimated in the previous tables.

In conclusion, the numerical results suggest that the CU agreement is not trade diverting; it raises welfare, output, GDP and trade volume in Turkey. Despite the higher demand of basic skilled labour, in line with the Stolper-Samuelson model, this trade agreement causes an increase in overall income inequality in the scenario with fixed wages, mainly due to the rising gap between rural and urban incomes as a consequence of the contraction of the agricultural sector still heavily protected by trade barriers. In addition, it seems that this trade policy, accompanied by a fixed real wage policy allowing the creation of new jobs, raises Turkey's welfare, GDP, and output far greater than in the case of flexible wages.

5. Conclusions

The aim of this study is to analyse the impact of the CU agreement between Turkey and the EU on the welfare and the size distribution of income among urban and rural Turkish households; and on Turkey's employment, sectoral output, GDP and trade flows. In order to examine the impact of the CU upon employment in Turkey, two main cases have been considered for the labour market: the standard case of flexible real wages with full employment, and the case of fixed real wages.

The numerical simulations show that the CU agreement with the EU is not trade diverting, raises the trade volume-GDP ratio and that resources are reallocated towards the industrial sector, which expands by 4.1%-5.4%. With regard to welfare, although aggregate gains are equal to 1226-2750 billions of 1990 Turkish lira, the impact on urban and rural households' welfare highly depends upon the assumption postulated for the labour market. In the scenario with fixed wages, urban households are better off and rural households are worse off; in the scenario with flexible wages, urban household are worse off and rural households are better off. However, in the fixed wage case, a large welfare gain in urban areas is accompanied by a negligible welfare loss among rural households.

The second important result is related to the issue of international trade and income inequality. Despite the owners of basic skilled labour being better off than both the owners of skilled labour and the owners of capital, in line with the Stolper-Samuelson theorem (as Turkey is a middle income developing country and, therefore, abundant of the basic skilled labour factor), overall income inequality measured by the size distribution of income might rise. In the scenario with fixed wages, the main source of income inequality is the inter-income inequality between urban and rural areas, which rises by almost 7%, due to an output fall in agriculture, a sector still protected and the principal income source of rural households. This result suggests that theoretical and applied analysis of trade impact on the distribution of income, carried out only with models which define household groups according to their functional role and under the full employment assumption, might be misleading.

As far as the issue of international trade and employment is concerned, if real wages are rigid, the preferential trading agreement with the EU leads to a rise in employment, as one would expect from the Krugman model applied to a developing country. The efficiency gains with trade, not being absorbed by a wage increase, generate the creation of 148000 new jobs (432000 in the case of a more flexible economy), mainly basic skilled non-agricultural workers.

Finally, the welfare gains and the incremental GDP would be larger, if policy-makers encourage institutions to bargain a wage rate, such that real wages remain constant. The sensitivity analysis on elasticities values confirm the overall conclusion that the preferential trading agreement with the EU, accompanied by a fixed real wage policy, creates new jobs in Turkey, raises Turkey's welfare, output and GDP far greater than in the case of flexible wages, but also increases income inequality.

Appendix A Numerical model: The CU agreement

This appendix reports the algebraic formulation of the numerical model employed to study the economic impact and the income distribution effects of the CU agreement between Turkey and the EU on the Turkish economy. The appendix has been split into eight sections: (i) equations related to prices; (ii) equations related to production and factor demand; (iii) equations related to domestic and foreign trade; (iv) equations related to income; (v) equations related to taxes; (vi) equation related to savings and investment; (vii) equation related to final demand and intermediate demand; (viii) equations related to the market clearing conditions.

[A.1] Price equations

$$(A1) \quad p_j = \Delta_j^{-1} \left(1 + t_j \right) \left[\zeta_j^{\varepsilon_j} p m_j^{C1-\varepsilon_j} + (1 - \zeta_j)^{\varepsilon_j} p d_j^{1-\varepsilon_j} \right]^{1/(1-\varepsilon_j)}$$

$$(A2) \quad p m_j^C = A_j^{-1} \left[\alpha_j^{\mu_j} p m_j^{EU1-\mu_j} + (1 - \alpha_j)^{\mu_j} p m_j^{RoW1-\mu_j} \right]^{1/(1-\mu_j)}$$

$$(A3) \quad p m_j^{EU} = \overline{pwm}_j^{EU} (1 + t m_j^{EU})$$

$$(A4) \quad p m_j^{RoW} = \overline{pwm}_j^{RoW} (1 + t m_j^{RoW})$$

$$(A5) \quad p y_i = \Phi_i^{-1} \left[\varphi_i^{\phi_i} p d_i^{1-\phi_i} + (1 - \varphi_i)^{\phi_i} p e_i^{C1-\phi_i} \right]^{1/(1-\phi_i)}$$

$$(A6) \quad pe_i^C = B_i^{-1} \left[\beta_i^{\eta_i} pe_i^{EU^{1-\eta_i}} + (1 - \beta_i)^{\eta_i} \overline{pwe_i^{RoW^{1-\eta_i}}} \right]^{1/(1-\eta_i)}$$

$$(A7) \quad pe_i^{EU} = \frac{\overline{pwe_i^{EU}}}{1 + qr_i^{EU}}$$

$$(A8) \quad pv_i = X_i^{-1} \left[\gamma_i^{s\sigma_i} w_i^{s(1-\sigma_i)} + \gamma_i^{u\sigma_i} w_i^{u(1-\sigma_i)} + (1 - \gamma_i^s - \gamma_i^u)^{\sigma_i} r^{(1-\sigma_i)} \right]^{1/(1-\sigma_i)}$$

$$(A9) \quad w_i^s = H_i^{s-1} \left[\sum_s \delta_{is}^{\xi_i^s} w_s^{1-\xi_i^s} \right]^{1/(1-\xi_i^s)}$$

$$(A10) \quad w_i^u = H_i^{u-1} \left[\sum_u \delta_{iu}^{\xi_i^u} w_u^{1-\xi_i^u} \right]^{1/(1-\xi_i^u)}$$

$$(A11) \quad \bar{\Omega} = \frac{\sum_j pd_j \bar{D}_j}{\sum_j \overline{pd_j \bar{D}_j}}$$

Variables ():*

AK_i Aggregate capital

\overline{BD} Budget deficit

C_j Private demand of goods

\overline{CA} Current account deficit

\overline{CAP} Aggregate capital stock

$CONTAX$ Consumption tax on fuel

D_j Domestically produced commodities

\overline{D}_j Domestically produced commodities in the base year

\overline{DEPK}^{agr}	Fixed capital depreciation in agriculture
\overline{DEPK}^{nagr}	Fixed capital depreciation in non-agricultural activities
$DTAX$	Direct tax
E_i^C	Aggregate exports
E_i^{EU}	Exports to the EU
E_i^{RoW}	Exports to the RoW
GC_j	Government spending on goods
I_j	Investment by sector of destination
\overline{INV}	Aggregate investment
L_{is}	Sectoral skilled labour
L_{iu}	Sectoral unskilled labour
LAB_s	Aggregate skilled labour
LAB_u	Aggregate unskilled labour
M_j^C	Aggregate imports
M_j^{EU}	Imports from the EU
M_j^{RoW}	Imports from the RoW
p_j	Price of the Armington good
pd_j	Price of domestically produced commodities

\overline{pd}_j	Price of domestically produced commodities in the base year
pe_i^C	Composite price of exports
pe_i^{EU}	Supply price of exports to the EU
pm_j^C	Composite price of imports
pm_j^{EU}	Domestic price of imports from the EU
pm_j^{RoW}	Domestic price of imports from the RoW
py_i	Aggregate producer price
\overline{pwe}_i^{EU}	Price of exports to the EU prevailing in the EU market
\overline{pwe}_i^{RoW}	Price of exports to the RoW prevailing in the RoW market
\overline{pwm}_j^{EU}	Price of imports produced by the EU net of duties
\overline{pwm}_j^{RoW}	Price of imports produced by the RoW net of duties
R	Government revenues
r	Rent on capital inputs
S_h	Household savings
SAV	Aggregate savings
$TARIFF$	Tariffs
\overline{TGC}	Aggregate government spending on goods
V_i	Value added

$VATTAX$	Value added tax on goods and services (Non fuel)
VER_i^{EU}	Rents from voluntary export restraints agreements with the EU
x_{ji}	Raw-material inputs
X_j	Aggregate intermediate demand
Y_i	Output by sectors
w_s	Wage of skilled labours
w_u	Wage of unskilled labours
w_i^s	Average wage of skilled labour
w_i^u	Average wage of unskilled labour
$\bar{\Omega}$	Aggregate domestic price index - numeraire

Parameters

a_i^v	Value added requirement per unit of sectoral output
a_{ij}	Leontief input-output coefficients
qr_i^{EU}	<i>Ad valorem</i> export quota premium
t_j	Indirect tax rate on goods and services
td_h	Direct tax rate on household income

tm_j^{EU}	Effective import tariff rates on EU goods
tm_j^{RoW}	Effective import tariff rates on RoW goods
α_j	Share parameter in the second nest Armington function
β_j	Share parameter in the second nest CET aggregation function
δ_{is}	Share parameter of skilled labour function
δ_{iu}	Share parameter of unskilled labour function
γ_i^s	Share parameter of the value added function
γ_i^u	Share parameter of the value added function
ε_j	Elasticity of substitution between imported and domestic goods
φ_i	Share parameter in the first nest CET aggregation function
ϕ_i	Elasticity of transformation between exports and domestic goods
θ_j	Investment share on commodities.
η_i	Elasticity of transformation among exports to different regions
ς_j	Share parameter in the first nest Armington aggregation function
τ_h	Household marginal propensity to save
σ_i	Elasticity of substitution among primary factors of production
ζ_h^{agr}	Share parameter of the agricultural capital income to households
ζ_{hs}^L	Share parameters of skilled labour income to households

ζ_{hu}^L	Share parameters of unskilled labour income to households
ζ_h^{nagr}	Share parameters of non-agricultural capital incomes to households
ξ_i^s	Elasticity of substitution among skilled labours
ξ_i^u	Elasticity of substitution among unskilled labours
ϖ_j	Fixed shares of government spending on goods
ϑ_{jh}	Fixed shares of household spending on goods
μ_j	Elasticity of substitution among imports from different regions
A_j	Shift parameter in the second nest Armington function
B_i	Shift parameter in the second nest CET aggregation function
X_i	Shift parameter of the value added function
Δ_j	Shift parameter in the first nest Armington trade aggregation function
Φ_i	Shift parameter in the first nest CET aggregation function
H_i^s	Shift parameter in the aggregate skilled labour function
H_i^u	Shift parameter in the aggregate unskilled labour function

(*) Parameter and variables with a bar are set exogenously

Appendix B The measurement of inequality

The study focuses on the inequality “within” and “between” urban and rural groups. The data source does not provide any additional information concerning the income redistribution within each income class group. Thus, complete equality between household members within each income class group is postulated and the income arithmetic mean for each representative household member of a given income class group, hr_h , divided by the so called “true” cost of living index, P_h , (Shoven and Whalley, 1992) is employed to measure income inequality.

Jenkins (1991) and Cowell (1995) investigate the properties of different measures of inequality widely used in the economics literature in a simple fashion. It can be shown that for θ approaching zero,

$$(B1) \quad \lim_{\theta \rightarrow 0} GE_{\theta} = -\frac{1}{K} \sum_{h=1}^H k_h \log \left(\frac{hr_h/P_h}{hr^m} \right),$$

and that for θ approaching one,

$$(B2) \quad \lim_{\theta \rightarrow 1} GE_{\theta} = \frac{1}{K} \sum_{h=1}^H k_h \left(\frac{hr_h/P_h}{hr^m} \right) \log \left(\frac{hr_h/P_h}{hr^m} \right).$$

As reported by Cowell (1984), the disaggregated version of the generalised entropy measure is given by:

$$(B3) \quad GE_{\theta} = \sum_{g=1}^G i_g^{\theta} m_g^{1-\theta} GE_{\theta w} + GE_{\theta b},$$

where $GE_{\theta w}$ and $GE_{\theta b}$ represent the inequality measure “within” and “between” each group g , respectively; i_g the share of total income held by g ’s household members; m_g the g ’s population share; and G the number of mutually exclusive groups, that is the urban and the rural groups.

$GE_{\theta w}$ is calculated as if each group were a separate population, whilst $GE_{\theta b}$ is derived by assuming that every household member within a given group receive the g ’s mean income (Jenkins, 1991):

$$(B4) \quad GE_{\theta b} = \frac{1}{\theta^2 - \theta} \left[\sum_{g=1}^G m_g \left(\frac{hr_g^m}{hr^m} \right)^{\theta} - 1 \right],$$

where hr_g^m is the mean income within the group in real terms.

Jenkins (1991) also shows that:

$$(B5) \quad \lim_{\theta \rightarrow 0} GE_{\theta b} = - \sum_{g=1}^G m_g \log(hr_g^m / hr^m),$$

and that

$$(B6) \quad \lim_{\theta \rightarrow 1} GE_{\theta b} = \sum_{g=1}^G i_g \log(hr_g^m / hr^m).$$

Appendix C Results of the sensitivity analysis

The figures reported in this appendix arise from the sensitivity analysis of the model to the elasticities values. The columns, which are stated “low”, show the counterfactual in the case of all elasticities divided by factor two. The columns, which are stated “high”, show the counterfactual in the case of all elasticities multiplied by factor two. The columns, which are stated “standard”, show the counterfactual with the regular elasticities as reported in the main text.
